Task-Based Information Searching: Research Methods

Sanna Kumpulainen

Library, Tampere University of Technology, Tampere, Finland

Abstract

It is widely agreed that searching is part of a larger task performance and that it should be studied in this context. To be able to reveal the process nature of searching, a task-based approach can be used. This entry discusses task-based approach and its use as a framework for field studies, discusses relevant task features, and presents some of the typical methods for studying task-based information interaction in the real-world context.

INTRODUCTION

This entry provides an overview for studying task-based information searching in the real-world context. In order to understand which methods to use in a task-based field study, one has to consider several aspects of the complex task-based setting. Since so little is known about the relations of searching and the underlying tasks, the study of information-intensive task performance requires research methods that are mostly exploratory and descriptive real-world studies. This allows reporting actual behavior with the contextual aspect. By using a task-based approach, the actions of the searcher with both the cognitive and affective aspects can be studied.

People search for information in order to better accomplish tasks at hand.^[1] Task trigger information needs,^[2] or anomalous state of knowledge (ASK),^[3] that lead to various information interactions, including searching. Task-based information searching entails a task that is conducted. When people perform information-intensive tasks, they tend to use the whole information environment available, including various types of information, search tools, and data repositories. During task performance processes, people use several tools in an integrated way to access various types of information. Typically, information-searching studies view at a small piece of the process at time or use only one search tool in a test situation, which lead to narrow understanding of the holistic process of searching. By using too narrow research setting, it is not possible to study the heterogeneous nature of the information source use or the task-related characteristics that affect the search situation. This complexity and the process nature of searching necessitate task-based fieldwork studies in real-life context.

Task-based information searching is a complex phenomenon influenced by contextual characteristics, searcher's personal traits, and the prevailing information environment.^[1] Contextual characteristics include the organization, its culture, and its information environment;

the task performer's traits, searcher's previous knowledge, experience with similar tasks. One should not forget the varying tasks themselves that affect information behavior. Learning from the experiences of the searchers requires data collection based on multiple methods and triangulation of the findings because no single method is reliable and sufficient in order to study the complexity of real-world searching. Further, there is not a common understanding what are the characteristics of tasks that actually affect the searching. If we understood better the tasks and their intrinsic search tasks, it would not only increase understanding of this important area but also bring more power to experimental test design or even user simulations.

This entry provides a short background, discusses tasks, task complexity and task-based approach, and lastly, gives an overview of some research methods, such as questionnaires, interviews, and shadowing, which are used in fieldwork in task-based information searching.

BACKGROUND

Nowadays, information access is ubiquitous and happens continuously—inseparable from the work task in many cases. In a matter of fact, information is searched in order to fulfill an information need, which is triggered by problems, situations, and daily activities people are in.^[1,4–7] Information searching does not occur in a vacuum but is an inseparable part of the surrounding activities, situations, and contexts.^[8] The situations people are in may call just some very timely information—such as a bus schedule—or aimlessly passing time, or they may require learning of new skills and knowledge creation in order to accomplish a larger goal. One way to frame the situations for research purposes is to use the task-based approach. Instead of looking at search tasks—querying one information system—task-based approach to information searching is taking the underlying larger task as a starting

point to examine information searching. During task performance, people may need some additional information that cannot be remembered or created with the existing knowledge. This need, which is also called anomalous state of knowledge,^[9] prompts information seeking. This might include asking a colleague, checking one's own notes, or searching an information repository.

Since the information searching occurs during a task, the searching should be studied, and evaluated, in relation to the task performance process.^[7,10,11] The focus is on the information interaction that happens during that process. A related term, information retrieval, has been defined as the study of how the system replies to a request, or as how humans interact with a system. The task-based approach adopts the latter view, but in a larger context. There has been a turn in information interaction studies from a search task setting into a wider perspective, taking the whole work task as a context of searching. In studying the searching in the context of a task, task-based information searching takes a cognitive viewpoint on information retrieval and human information activities.^[1] This viewpoint entails the idea that personal information needs should be treated as potentially dynamic contrary to the static view in traditional information retrieval research.

Searching, even when studied during work task performance, is tightly coupled with the use of information systems or search tools. These tools are used in order to get to the contents, not just to interact with the system interface. Information searching entails the whole cycle from the searcher's cognitive state to the representation of the information itself. While much is known about how systems work in retrieving documents, there is lack of knowledge on the user side and of how searching relates to task performance, how people use the information tools available to them, and where the tools fail to meet their needs.^[12,13] Understanding and exploiting contextual information may transform how people perform information discovery, analysis, and synthesis tasks.^[1] In order to build better tools, our understanding about searchers, underlying information environments and tasks, and their interrelations is crucial. In case of studying interactive information systems, in order to know the "goodness" of a system, their ability to advance the underlying task should be tested.^[10]

Information searching has been both studied with experimental settings in laboratory conditions and as natural settings in the real world. These branches of research differ from their research goals and methods.

Both are needed and the first approach seems more common at this point of time.^[11] Although these branches have different goals, there are some connections in between: real-world studies may reveal something that can be further tested in laboratory conditions. In order to test something relevant, one should know first what to test. This knowledge is gathered by field work in real-life situations and exploratory and descriptive studies of this kind

may inform hypothesis formation to be further tested in controlled experimental settings.

Experimental settings usually entail researcher involvement and controlled environments and report quantitative results. Some of these elements may be included in field studies as well, but usually fieldwork occurs in natural environments without any excessive researcher involvement. Moreover, usually in experimental interactive information retrieval and search studies tasks are seen as a vehicle for research,^[14] whereas in fieldwork tasks are regarded as inherent part of human daily performance. In controlled settings, it is very demanding to create long-lasting task processes with assigned tasks and therefore experimental studies commonly use more limited search tasks.

Fieldwork studies are intended to observe how real people search in order to complete real tasks. However, experimental studies in information searching are intended to study particular effects of the selected variables on human or system behaviors. This requires control over the situation. In experimental research designs, assigned tasks help with controlling the setting. Assigned tasks are hard to design and they may lack contextual features or personal aspects such as motivational or affective triggers that, in the real world, are present in search processes. Borlund^[15] and Wildemuth and Freund^[16] provide recommendations on how to design assigned tasks. Despite the challenges in designing tasks, there are experimental studies that have incorporated exquisitely real-world features.^[17,18] In these studies, assigned tasks are designed to reflect real-world situations.

The present entry focuses on fieldwork methods. The aims of fieldwork lie on understanding how people behave with the tools they are used to work with and during the tasks they are doing. Nevertheless, for those more interested in experimental settings, Kelly^[14] provides a broad overview on how to study interactive information retrieval and evaluate systems with users, Kelly and Sugimoto,^[19] a recent review on interactive evaluation research, and Wildemuth et al.,^[20] a review on assigned task difficulty and complexity in experimental settings.

TASKS IN TASK-BASED INFORMATION SEARCHING

A task is an activity to be performed in order to accomplish a goal.^[6] Task-based information searching is interested in the information interaction related to the task performance. A task at hand may be either a leisure or work-related task. It is seen as a triggering force behind the information needs,^[21] or ASK,^[9] possibly leading to information searching. According to Järvelin and others,^[11] it is a part of a larger task performance process, which can be cut down into activities, searching being one of them. Searching is one small part of the larger task,

among other activities, that are all aiming at task fulfillment.^[11,22]

Task Granularity

Human task performance and searching may be examined in different context and on different levels of abstraction.^[1] Tasks are interpreted at multiple levels of granularity, and this is related to one's understanding about the task.^[22] Task doer needs to understand the preconditions and goals for performance. As her understanding about the task increases, and if the focus is formulated, she is more capable of decomposing the task into smaller pieces. These pieces are conceptualized as stages,^[23,24] during which the cognitive and affective states evolve, or as successive subtasks or actions,^[11] which advance the fulfillment of the task.

Byström and Hansen^[22] look at the task granularity as a hierarchical structure, where information-seeking tasks are part of a larger (work) task, and search tasks are part of an information-seeking task. They also discuss information use as an essential part of a larger task and as a contributing factor in task accomplishment. Järvelin and others^[11] decompose a (learning) task into five cognitive and behavioral activities, which are task planning, searching information items, selecting between them, working with them, and synthesizing and reporting.

Similarly to Byström and Hansen's levels in their task hierarchy, Kekäläinen and Järvelin^[25] present a nested model of context to evaluate information searching.^[1,25] They separated sociocultural, organizational, the work task, the information-seeking task, and the information retrieval levels. Tasks may be analyzed on these levels as task descriptions or goals. All these levels are present in a task performance process and the phenomena during task performance may belong to varying contextual levels.^[26] The contextual levels also outline the methods and the participants in the study to some extent. On the socio-organizational level, research interest may lie on decomposing networked phenomena and identifying its actors.^[27,28] On the organizational level, one may be interested in task flows in the organization and of division of labor, etc.,^[29] or studying on the high-level task context in collaborative information searching during teamwork.^[30,31] This entry, however, takes the view of studying one individual at time, but similar settings may also be applicable to groups of people.

Typically studies on information searching take the search task level as a starting point. However, in real world the goals and constraints of the tasks are derived from higher-level tasks.^[1,24,32] Taking the higher-level context into account, the missing links between larger tasks and search tasks may be found. The larger, motivating task is binding the subactions together, which might seem atomistic if separated from each other. If just the single search task is taken as a starting point, one system

setting might seem reasonable. However, if the scope is broadened toward a larger task, one may have to accept the whole information environment composed of multiple types of information systems providing heterogeneous data or information, such as audio, pictorial, numerical, or text data. The actual information is created during the process, collected piece by piece from various sources and finally interpreted and used in knowledge creation.^[33] The task has several features additional to the granularity one being the task complexity, which is discussed next.

Task Complexity

Task complexity and difficulty are very commonly integrated in information searching research.^[20] Research in information searching has discussed task complexity from both objective and subjective perspectives. These two perspectives have different background. Objective task complexity supposes "an objective task external to and independent on task performers."^[34] In the objective task complexity, the structure of the task and aspects related to the task are used in assessing the task complexity. The increasing number of choices (paths) leading to the desired outcome increases task complexity. Objective task complexity is the complexity of the prescribed task seen by the person prescribing the task, and subjective task complexity is the complexity of the actual task for the task performer executing it.^[34]

Tasks may be difficult to perform by many factors; for example, there might be too many alternatives to consider, imprecise or missing raw data, a great deal of irrelevant information, lack of ideas, or insufficient methods.^[1,35] This characterization, which considers the features of the task, treats complexity as a function of objective task characteristics.^[36]

Further, Campbell^[36] and Liu and Li^[34] consider task complexity as composed of number of subtasks. Albertson and Meadows^[37] use similar construction: complex search tasks contain multiple subtopics. Objective task complexity may be defined also as the number of steps required in order to reach the completion. Li and Belkin's^[38] comprehensive task categorization uses both objective and subjective characteristics. It is based on earlier categorizations in information research literature and includes a number of dimensions, which may be divided into objective and subjective parts. Objectivity here means the number of paths between which the task performer has to choose during the task. The subjective aspect in the categorization is called difficulty.

An example of more subjective approach is a priori task complexity. Byström and Järvelin's^[39] approach to task complexity is an intersection between the task and actor characteristics: it evaluates task complexity on the basis of the actor's a priori understanding about the features of tasks—namely the information needed, the process, and the outcome. If all the aspects are known, the

task is routine, and if none, the task is considered as complex.^[39,40] There are different levels in between. In complex tasks, the actor lacks a mental model sufficient for enabling him or her to assess what needs to be done. The a priori task complexity has been used in field studies because it does not require subject expertise. In a priori task complexity, the task performer's previous knowledge on similar tasks affects the complexity assessment, because the more experience the person has with similar tasks, the more focused the conceptual structure of the task.^[41] Byström and Järvelin's^[39] a priori task complexity has been applied also to some extent by Bell and Ruthven,^[42] Kumpulainen,^[40,43] and Kumpulainen and Järvelin.^[26,33]

Both objective and subjective views on task complexity may be employed in fieldwork. However, if a person does not know what the outcome is or cannot describe the possible paths, it is very hard to count or consider the different aspects or the paths to the completion. In fieldwork, the task complexity can be assessed only after the task performance, when all the queries and needed steps or subtasks are already conducted.

However, researchers cannot be sure during fieldwork that the participant is actually going to end the task during the research time period. Therefore, the a priori task complexity may be more useful in real-life studies. This way, a task complexity assessment can be collected for all task performance sequences even if the task processes do not reach the completion. One should keep in mind that natural research settings include always some compromises and instability. Therefore, because of the (possibly) uncompleted and incomplete tasks, it is hard to compare different task performance sessions with another ones if one uses the objective complexity and the numbers of subtask constructs, or the total number of paths, are needed.

Whether the task is self-formulated or assigned, it is the perceived task that is performed after all. The perceived task is the task performer's current understanding about the task goals and the suitable path(s) leading to that goal. This means that people who have the same assigned task treat it according to their understanding. This perception may change during the task performance due to learning about the task itself. Perception of the task and possible solutions are evolving and getting clearer toward the end of the process. One critical point is the focus formulation phase, during which the actor creates a clear understanding what the task is about.^[23,41] Focus formulation allows the searcher to make pertinent judgments about the retrieved items. Without this formulation, a task can be performed, but the outcome might not be good.^[44]

The Process Nature of Searching

Task performance and searching are evolving, iterative processes. According to Toms,^[32] the process of achieving

the task outcome determines the success in task performance. Therefore, tasks and search tasks internal to them should be studied as processes. The processes may be decomposed into smaller events. There are models that look task performance in stages,^[23,24] and models that decompose tasks into subtasks, which are performed as series of actions.^[11,43,45,46]

One of the early stage models was the Kuhlthau's ISP model.^[23] The ISP model consists of six stages, during which the information search process evolves, and the searcher formulates a focused understanding about the topic. According to the model, this point is critical since the focus formulation enables the searcher to assess the relevance of information items. Kuhlthau's model examines the searching process at levels of physical actions, cognitive and affective aspect, and it was developed to inform librarians. Vakkari's^[24] task-based information search model was based on the ISP, and it consisted of three stages. Both models used stages, and the searcher moved from a stage to another in the course of searching. Models in information searching research that decompose task processes into subtasks are not very common. A very recent model of Järvelin and colleagues^[11] decomposes a learning task into five subtasks and discusses program theories^[47] of these subtasks as a tool for information retrieval evaluation.

The berry-picking model by Bates was one of the first models that described searching and exploration task performance as a process.^[48] It was developed in an OPAC (online public access catalog) environment, which included references to full texts. Bates' berry-picking model is based on the idea that pieces of information are collected from separate documents or information objects during the search, and the understanding about the task was created during the berry-picking episodes. This is a natural way humans explore their information environments, and this applies also to web environment.

The study of task-based searching as a process entails that the subtasks, the search stage, or phase should be taken into account. The process of searching affects the searchers' understanding about the task itself, the perceived utility of information, and what will be the next step in the process. Together with the procedural approach, task features such as complexity and granularity are worth consideration in research setting. Due to their complexity, these task-related phenomena often require multimethod research. In the next section, we discuss some of the methods that may be used in task-based field studies.

STUDYING TASK-BASED INFORMATION SEARCHING IN THE FIELD

Due to the complexities of studying information searching during tasks in their context, it requires multiple and often

tedious means of data collection. The traditional means of data collection for studying human actions include questionnaires, interviews, diaries, and observation.^[1] The quality of results obtained from field research depends greatly on the data gathered in the field.

There are some field studies that relate searching to larger tasks. Typically, the type of task-based research uses multiple methods. To review a few, Byström and Järvelin^[39] studied information seeking related to tasks in municipal administration through diaries and questionnaires. Saastamoinen and others^[49] revisited this study and studied how task complexity was related to the information types in municipal administration by using task shadowing and questionnaires. Kumpulainen and colleagues,^[33,40,50] Huuskonen and Vakkari,^[51,52] Freund and colleagues,^[53] and Markkula and Sormunen^[54] used shadowing combined with some other method. Kumpulainen and colleagues^[33,40,50] examined how query types and the use of various systems varied according to task complexity in molecular medicine. They used shadowing, interviews, logging, and photographs. Huuskonen and Vakkari^[51] studied by using worksite observations and interviews, how social workers record and use information in a client information system during various tasks. Freund and colleagues^[53] used a multimethod approach using focus groups, interviews, shadowing, and resource audits in their study on software engineers' task-based information behavior. Markkula and Sormunen^[54] used interviews and task observations to study the work processes of journalists, which included various stages, and these stages shaped information access and interaction.

Attfield and Dowell also studied journalists, but they used interviews and grounded theory for analysis.^[55] Bartlett and Toms^[56] also used interviews as a data collection method in their study of biotechnology experts work tasks and made a detailed task analysis showing each subtask in the workflow. Vakkari and Huuskonen^[44] used questionnaires, search logs, and expert outcome evaluations in their study, which analyzed which aspects of search process and search output were associated with the task outcome in medical students essay writing assignment.

Consequently, it seems that multiple methods are used in studying task-based information searching. In the following, we discuss the typical methods used and data triangulation, which facilitates the in-depth study of complex task performance sessions.

Questionnaires

Questionnaires are a very economic way to collect data and are typically used to study topics that are already known to some extent. However, like all the methods represented in the entry, questionnaires can be used in different types of research settings.^[57] Firstly, exploratory research questionnaires benefit from open-ended

questions, which allow deep understanding and some unexpected findings. Second type is descriptive survey, which may be used, for example, in collecting opinions about some issue, and typically includes multiple choices and predefined categories. This type is considered as conclusive due to its quantitative nature. Thirdly, one may use questionnaires in explanatory studies in order to study the causality. In explanatory research, careful preplanning of the questions is required. The aim is to explain the cause and effect relationship between variables. Causality may be studied to reveal which variables are the cause and which are the effect and to study what is the type of the relationship between the causal variables and the effect to be predicted.

Questionnaires are usually understood as a means of quantitative research, but they can be also used as a qualitative manner with open-ended questions in an exploratory research setting. The questionnaires in information searching and seeking studies are typically circulated among some social group or staff in an organization, so everyone in the target group is included. Therefore, no actual sampling method is used.

The value of collected data completely depends upon how well respondents answer on questionnaires, and, on the other hand, how good the wording in the questionnaire is. Usually, an explanatory survey is based on a theory from which a hypothesis is derived and the concepts are operationalized. However, in task-based approaches one useful way is just to survey in an exploratory or descriptive manner, for example, what is the perceived information environment like, what are the populations preferences for suitable information tools and to survey what kinds of tasks they perceive doing.^[58,59] This kind of research is typical of task-based searching studies. There is no attempt to explore why a phenomenon occurs, but just to state that it does. This is the case if very little is known about, for example, the tools people use in their daily activities. However, since the control over how people respond to a questionnaire is low, questionnaires also benefit if used in combination with some other methods.

Nowadays, questionnaire studies are typically published in web form and a link to the form is distributed via web home page or email. Via web questionnaires, researchers are able to reach large groups of people quickly and simultaneously, they are easy to handle, and the data are already structured in suitable form for further analysis (e.g., a spreadsheet form). However, web questionnaires may be subject to a bias toward certain groups (active, willing to answer, tech savvy, etc.), and they typically suffer from low response rates. Web questionnaires also suffer from the same deficiencies as the paper form questionnaires: it is hard to capture the meaningful aspects of human actions and to place the actions or phenomena that are captured in any context in which they occur—not to mention the process nature of searching. Further, questionnaires have been criticized to block creative thinking

and imagination beyond the research setting.^[60] However, despite the criticism, open-ended qualitative-style questionnaire studies are very useful in the case the researcher does not know much about the field and needs to get a quick overview of the information environment the people are engaged with and their opinions about it.

Interviews

Interview is one of the major approaches of data collection in qualitative research. Interviews are the best way to collect in depth data on how people understand or feel about phenomena in their everyday lives.^[51] It is a means to uncover their experiences and the meaning of these experiences. Interviewing is a good method of studying the “why” questions, and interviewing is focused in comparison with shadowing; one does not have to see everything. During the interview, the researcher creates a personal contact but access to the field is easier than when observing.^[50]

Maybe the most used type of interview in task-based studies is a semistructured interview. In this type of interview, the interviewer has broad themes and topics, which are discussed, and the interviewer steers the situation toward the central topics. Preparation is important to be able to steer, and the interviewer should make an interview guide, which includes all the topics that should be covered. In semistructured interviews, the interview guide keeps one on track but still allows her to collect unlimited qualitative data.

There should be a clear purpose for the interview. During the whole interview, the interviewee must feel confident to talk freely. The flow of conversation should be kept going and the interviewer should listen actively and keep the questions simple. However, interviews are open to bias and problems. Opinions regarding behavior are not the same as actual behavior, and the respondents may not correctly remember the answers to questions or they might be unwilling to tell the flow of actual events. People are not good in recalling simple tasks that are executed on a routine basis or exact protocols they follow. More precise accounts of actual behavior are collected by observation, but interviews are very useful when collecting data about people’s interpretations about their tasks (e.g., perceived difficulty) or opinions about the search tools they use.

Critical Incident Technique

The critical incident technique is a set of procedures used for collecting the observations of human activity and behaviors.^[61] Typically, the participants are asked to recall a recent incident that has relevance to the research questions, and it is used as a vehicle for interviews. The participants may answer the interview questions by reflecting their actions related to that recalled incident or demonstrate their behavior during that recent incident.

This helps the participants to anchor their thoughts and behaviors to a certain incident, and may introduce some reality to basic interview settings. Critical incident technique is suitable for collecting data in the field and in more controlled environments. Critical incident technique is a very flexible method and helps to bind the findings to practical real-world tasks. In task-based information searching, the participants are asked to recall a recent task that included any information-searching episodes. Then, they are interviewed about the causes, descriptions, and outcomes of the task. The actors’ feelings and perceptions of the situation are collected and the actions taken during the task are either interviewed or demonstrated. These scenarios can be presented as narratives, visualized in diagrams, or as a causal model. Examples of use of the critical incident method are research by Zach,^[62] Auster and Choo,^[63] and Roos and others.^[58]

Critical incident method can be used also as a vehicle for observational research.^[51] The participants are asked to recall a recent situation or a task and to perform the task. Task may be observed at the participants’ work place, home, or any other place or environment where the critical incident task has been previously conducted. Also, making people recall a recent task is a good way to bring naturalistic tasks into experimental settings.

This method is very flexible and suitable for studying everyday problem solving, but its challenges lie already in the remembering of the task. The tasks that are recalled tend to be rather simple, and the participants may remember the actual behaviors imprecisely and present idealized workflows. This method, however, helps to bind the searching activities and the underlying task together and it may help in revealing the procedural nature of task performance.

Diaries

Diaries are a good way to collect data on participants’ recollections of transactions, such as tasks and used information systems. Usually, diaries are collected with structured forms and diaries are filled after a workday or task performance. People are asked to describe relevant actions and, for example, information sources they used during particular task performance processes. There might be questions about reflecting the events or their features, which relate to the research questions. Therefore, in addition to just collecting the events, diaries provide clues to the importance of events for the participants and their attitudes about those events. Diaries also provide data in textual form, which is easy to analyze compared with voice recordings, for instance, or video diaries. Diaries may be collected via web forms, so that makes the data even easier to handle. Diaries can be a useful strategy for data collection when periods of prolonged participant observation are not practical. This might be the case in

order to have a rich source of data of reflections that communicate the stories of their daily lives.

Usually in task-based studies diaries are used in combination with some other data collection method. Byström,^[39,64] Hansen,^[65] and Saastamoinen and colleagues^[49] used diaries in their studies and triangulated the data collection with some other type of data, such as interviews and shadowing. They collected information about the participants' reflections on the task complexity and the use of various information resources, among other things. However, despite the usefulness of diaries in some occasions, participants may find filling in the diaries time consuming and cumbersome. If the diaries are not collected during observations, the researchers cannot know how long after the event the diary was actually made and, consequently, the events might be not remembered correctly. Processes may be collected with diaries, but as discussed previously, they are a means of collecting recollections. People do not describe sequences of actions precisely and sometimes they even tidy up their descriptions of performance. Instead, they tend to describe idealized procedures leaving out some workarounds or problems.

Shadowing

Shadowing is a qualitative method, which involves a researcher closely following people over a period of time to uncover the real-time actions performed in some context.^[66,67] It enables the study of information searching in context of real everyday practices and situations and reveals such barriers and routine like workflows that people are not actually aware of. Shadowing facilitates the study of complex tasks and task processes as they are and it is a very agile method. As it is known, people are not good in describing what really happens, but they describe their ideal ideas how things go. This is not necessarily what actually happened. Shadowing can be done over long periods of time or applied more rapidly to gain a quick understanding about a problem.

Before starting the shadowing, it is important to get to know both the organizational environment and the information environment they work with in case of studying information searching. Without knowing what the participants refer to makes it very hard to follow the flow of actions at the start of shadowing. Also, taking some time to carefully select the participants and the venue is important: participants need to take the actions that contribute to the research questions. It is of high importance to carefully select suitable participants for the study. The investigator should be aware of the current tasks the participants are going to conduct, and the shadowing sessions should be arranged so that the kinds of actions, for example, searching, really occur during the shadowing. One practical way is just to simply ask the participants that when they have planned to do some searching and arrive at that point of time to collect the data.

The shadowing method does not require undistorted situations. The participants certainly are aware of being shadowed, and this may have an effect on their behavior and task performance. However, nearly all participants usually become comfortable with the situation after a short while. The method is about gaining an "inside view" of the research questions. Throughout the shadowing period, be it few hours or several months, the researcher asks questions, which will prompt a commentary from the participant. Some questions will be for clarification, other questions to reveal a purpose of actions. During the shadowing, the researcher will write a continuous set of field notes. Shadowing yields data that is more detailed than data gathered through many other data collection methods. Shadowing does not collect the accounts of participants' opinions but observes it directly and gives the researcher first-hand detailed data both on aspects that are habitual or mundane, and the problematic to express, which may be otherwise difficult to collect.

A task is performed in task sessions. These task sessions are observed. During a task performance session, a person is working on a particular task. There might be several ongoing tasks over time, but just one session at the time is performed. Multitasking or parallel task performance means that people switch between the tasks. An actor starts at some point, for example, in the morning when she comes at the working place, or just stops the previous task and changes to another. There might be interruptions during the task, but the task session may continue after the break.

One important aspect in shadowing is to build trust. If the participant does not feel comfortable, critical information could be missed. The researcher must continually work on the personal relationship throughout the shadowing period. By providing information on what purposes the collected data is used and to allow participants to discuss the suitable shadowing times might help the participants to feel they have some control. The agreement that the shadowing may be stopped or paused at any time if it gets too distressing also eases the participants' situation.

Shadowing produces a massive detailed data set that is rich and thick in every aspect. Also, shadowing is a physically and cognitively burdening method for the researcher. It is not easy to follow people around day after day and still trying to stay focused. One of the questions that are of main importance is to keep the research questions in mind all the time, and not "going-native," which means adopting the views and opinions of the research participants. One of the biggest challenges in shadowing is the data handling.^[66] The researcher should already before the fieldwork plan how to collect the data and how to analyze it. This also brings more focus to the fieldwork. For collecting the notes, a pen and a hardback notebook are the best. The data handling might be assisted by the use of smart pens or other devices. With the handwritten

notes, the researcher already creates a focused view on actions, and so a part of the first-round analysis is already done. Video recordings of several hours are hardly usable, but it can be used if one needs detailed data on a short occasion.

Transaction Logs

A transaction log is “an electronic record of interactions that have occurred between a system and users of that system.”^[68] There are basically two ways to collect transaction log data, namely client-side or server-side log data. Client-side data collection may be more intrusive than server-side, but it is more accurate and can reveal participant’s interactions with the whole information environment via varying channels^[33] while server-side logs reveal the interactions with materials on one server. Both have their advantages providing detailed data on user behavior, and they allow studying the process nature of searching. However, the log data lacks depth and are ineffective as a methods of gaining an understanding of the underlying motivations, affective characteristics, cognitive factors, and contextual aspects that influence task-based information searching.^[68] User intent analysis based solely on transaction logs has been described as guessing.^[69] This is because similar queries are used for quite different search goals. Even an obvious known item search (e.g., for a homepage) may in fact be an unknown fact search (for an email address). However, this method is very valuable if used in a concerted way with some other (qualitative) method, such as shadowing or questionnaires. Despite its benefits, the biggest obstacle to successfully use client-side logging is that organizations or participants may prohibit any data collection on their computers.

Triangulation

Triangulation means the use of two or more methods of data collection in the study of some aspect(s) of human behavior.^[70] In other words, it refers to a multimethod research. Although triangulation may be of combining theories, methods, data sets, and investigators in the study of the same object,^[70] in this entry, however, the focus is on triangulating the methods. Triangulation advances the study of circumstances when a complex phenomenon requires analysis when some controversial aspects needs studying or when an established approach provides a limited and perhaps distorted picture and where a researcher is engaged in a case study. These all are conditions for a task-based information searching study.

Triangulation of methods raises the research above the possible biases related to the personality of the researcher that stem from a use of a single method.^[70] Using more than one method to examine the same research question enables the strengthening of the validity and confidence of the findings. However, sometimes research methods may

show opposite or discrepant events. In this case, the researcher should interpret why this happened and maybe use just one source of data in the analysis. However, there should be an understanding, which is the main data and use that in the interpretation of analysis. By the use of data triangulation, qualitative information can be added to flat quantitative data, such as questionnaire or log data, and more accurate quantitative data may increase the validity of the qualitative data.

Even before the data collection, the researcher should have some understanding about how the analysis will be done. After the triangulated data collection, data need to be merged. By collecting various types of data during the information intensive tasks, researchers should find a way to ensure that they know which data are connected to which task in possibly separate data sets (e.g., time stamps and personal account on log data). In the task-based studies, the point of departure for analysis is the task as a unit of analysis.^[64] One way to study the processes of tasks is to analyze the data as task performance sessions. A task performance session is the period of time, during which the participants are conducting a particular task; if the task is ended or changed, the session ends. This can be done by merging all data about each task performance session and then analyzed it together.

Fig. 1 depicts an approach to frame a task session. It has been used in Kumpulainen’s^[31] studies in task-based information searching in the biotechnology domain. In the procedure, every time a participant starts a task session, the participant is interviewed about what is the aim of the task, how well the participant is able to describe the task content, what information and which sources are to be used, and with which procedures the task is to be performed. These questions aim at assessing the a priori task complexity. During the task performance, field notes and interaction logs were collected. When the participant indicates that the task session might be at the end, some questions take place that ensure the ending of the session. Participants may switch to another task, stop working, or just have a break and continue after a while.

After framing the task sessions, other aspects related to research questions, such as task complexity, type, or stage, can be analyzed. Data may be analyzed using qualitative methods, for example, by classifying, the grounded theory

Fig. 1 Task session procedure for triangulation of interview data, transaction logs, and shadowing field notes.

approach, content analysis, visualizations, etc., or by quantifying it. One option to analyze the data is task analysis, which is a way to do detailed task decomposition.^[56,71] If task analysis is too fine grained, processes may be studied also by event analysis.^[72]

Ethical Concerns

Always, when using humans in research, an informed consent is needed. The researcher needs to think about the confidentiality and protect the identity of the participants. Participants should be informed about the purpose of the investigation and the main features of the research design. There might be some confidential material that the researcher is exposed to during the research, and the way shown to address this kind of material should be agreed in advance. The researcher should cause as little harm to the participants and their organizations or social environments as possible.

CONCLUSION

Real-world information searching is a combination of inquiry, discovery, and serendipity. It is nonlinear and iterative and entails the use of various heterogeneous information types from wide ranges of sources. By task-based studies, we are able to more realistically describe the human behavior during a task performance process, and by this inform not only system design, but also other highly controlled research settings such as simulation studies. On the downside, field studies focus on a specific organizational setting or a specific domain, where limited number and type of tools and data are used in tasks typical to that domain. The specific findings cannot be generalized to other contexts. However, it is not yet clear how the searcher should be modeled or simulated, so there is a world still to discover. Fieldwork remains under pressure due to costs and resource demands, but it still is an invaluable way to study how things really happen.

The existing models of task-based information searching suggest that task performance and information searching are processes that should be studied longitudinally over several work task performance sessions and search sessions. The task-based research is still uncommon, and there is still a need for investigating how and what features of tasks affect the searching. Therefore, the task-based approach provides a useful framework to study complex situations during information intensive work tasks, and further, a means to reveal the procedural nature of searching.

Taxonomy

Andrew Grove

Guest Faculty, Information School, University of Washington, Seattle, Washington, U.S.A.

Abstract

Taxonomy reflects the human instinct to organize. Once limited in Western culture to certain natural sciences, in the early twenty-first century, it has expanded to many domains, practices, and uses. Domains now include almost anything of interest, but particularly those motivated by business needs. Practices and uses include description, analysis, prediction, mapping terminology, information access, representation of knowledge, and tool-building. For information science, taxonomy is a powerful tool for connecting information content with information consumers effectively and efficiently.

INTRODUCTION

The practice of taxonomy reflects the human instinct to organize our experiences and perceptions of the world. Many organisms categorize objects: the practice is essential to survival, if only to classify possible food sources as edible or inedible, situations as safe or dangerous, environments as habitable or inhabitable, and so forth. Once such classifications are made, new experiences, objects, and situations may be placed in them, thus simplifying mental processes and interaction with the environment. Humans have developed this instinct to a high degree of sophistication, possibly because of the ability to perceive and process a great many details about the physical world they inhabit. But for people, organization goes far beyond survival needs. It inhabits the very core of human understanding and knowledge. With organization, facts and data become information and eventually knowledge, a rich source of philosophical discourse. Even for those not philosophically inclined, organization of information is an essential part of truly understanding and knowing a topic. According to cognitive psychology, all humans classify; the associations formed by classifying afford economy of thought for understanding the world.

Furthermore, classification may be the earliest technique of scholarship, and classifications provide building blocks with which to construct understandings.^[1,2] Many teachers believe that thoroughly understanding the terminology of a discipline is at least half the task of learning it; using taxonomy is one very effective path to such learning. Classification enables children to identify objects correctly, and they use it extensively.^[3] Organizing and classification is a useful vehicle for communication; if several parties agree on organization, they have a solid foundation for agreement on meaning, and therefore, mutual understanding. Finally, organizing things is one component of manipulating the environment; for humans, that is an essential

survival mechanism. Thus, even at its most abstract, organization has roots in the continuation of life. That makes it a deeply seated, perhaps essential, part of living.

Given the universal practice of organizing things, it is remarkable that only in the most recent 2500 years of human history has attention been paid to the principles and practice of categorization, classification, and taxonomy. Once almost exclusively the domain and practice of the natural sciences, taxonomy is now practiced in many other disciplines and venues, including the social sciences, computer science, information science, linguistics, cognitive science, and Internet site design and construction. Within these fields, taxonomy has acquired a wide range of meanings no longer restricted to the classical understanding of biology.^[4–6] Taxonomy is now applying its early sense of organizing things in accord with particular principles (“taxis”: arrangement; “nomos”: law) to a broader range of domains after several centuries of limitation to biology and other natural sciences. In the 1990s, taxonomy was redefined as any semantically significant, systematic organization of content^[7,8] or as the process of developing such organization.^[9] This definition sometimes includes any collection whose individual elements have been assigned to various nodes of a classification system. Thus, taxonomy is sometimes considered the process of matching collection items with predefined labels, and sometimes it is the creation and arrangement, as well as the resulting product, of the classification system itself.

A much overlooked and seldom discussed motivation for taxonomy is the desire of humans to communicate. Understandings of meaning contribute significantly to the human experience; shared and mutually agreeable understandings facilitate communication and connection, a fundamental goal of humans (and possibly other creatures); differences often generate undesired outcomes. Taxonomy, because it organizes entities using representations

of them (usually words), creates and facilitates language agreement; users of any particular taxonomy implicitly (and sometimes explicitly) agree upon the organization represented and, equally important, the terminology and semantics.

Taxonomy, in and of itself, through the process of organization and creating (or making explicit) agreement of language, performs an important and valuable role—describing the human experiences and perceptions of the world. When integrated with tools and processes for further exploration and discovery, dialogue and communication, taxonomy can perform a role central to the success (or failure) of such tools and processes; and, through them, the fundamental motivations for their existence and operation: making sense and communicating.

HISTORY OF TAXONOMY

Although Aristotle receives credit for setting out principles of biological taxonomy, one of the earliest recorded taxonomic structures is from the Book of Genesis, “These are the sons of Ham: Cush, Mizraim, Put, and Canaan. The sons of Cush: Seba, Havilah, Sabtah, Raamah, and Sabtechah. . .”^[10] a genealogy of the descendents of Ham (and, by extension, Adam), which predates Aristotle by many centuries. The *Historia Animalium* by Aristotle (384–322 B.C.E.) based taxonomy on the concept of grouping entities because of inherent properties, which collectively define similarities and differences. Properties are determined empirically, by examining many specimens for such characteristics and is an inductive process from observed examples, resulting in a lexical definition.^[11] According to Aristotle, important properties included mode of reproduction and habitat, as well as form.^[12] Aristotle’s basic methodology is still in use, although with some refinement. Linnaeus (1701–1778) introduced the practice of deriving the various levels of a taxonomy from the properties of the organisms or objects in the entire collection. With this development, he prepared the way for later scientific work involving the collection and examination of minute details of many specimens. His procedure contrasted with the practice established by Aristotle and is now commonly called bottom-up classification. By the time Darwin (1809–1882) wrote *The Origin of Species* in 1859, enough data had collected that additional principles of grouping division were necessary. He proposed that evolutionary lineage be considered as one criteria for the classification of species. Thus began the transition of biological taxonomy from a phenetic (observable characteristics, such as form) basis to a phylogenetic (evolutionary history of genetically related groups) basis. This eventually resulted in the ongoing debate whether evolutionary history is a necessary and sufficient criteria or only one of several to consider for accurate classification.

TAXONOMY

Classical Taxonomy

Taxonomy, as developed by Aristotle and refined by Gessner, Ray, Lamarck, Linnaeus, and Darwin, is a form of classification in which objects in a collection are grouped into nested subcollections based on observed similarities and differences. Such analysis has the goal of systematically organizing information and knowledge of organisms.^[13] In this sense of the word, taxonomy, as applied in biology, has been called systematics. Although different methodologies have been practiced, the basic principle has remained the same: entities are classed on the basis of inherent properties.

In biology, taxonomy is used to develop classifications of living organisms according to characteristics of form and evolutionary history and to assign newly discovered organisms to existing classifications. These classifications have developed into hierarchical systems composed of lineages, or branches, progressing with increasing specificity from common origins to increasingly divergent specializations, or species. At the top of the hierarchy are five kingdoms: animals, plants, fungi, protista (predominately single-celled organisms), and monera (bacteria). Under these kingdoms, organisms are arranged into at least six ranks, each more specialized than the preceding: phylum, class, order, family, genus, and species. An organism is always classed at least as specific as the species, and possibly more specifically if it is identified as a subspecies, a varietal, or a hybrid. Although most taxonomists are in general agreement concerning the assignment of various species to particular genera, wide disagreement can exist for assignment of genera to family and even more so respecting family membership in particular orders. For some kingdoms, there is dispute whether some of the categories actually have meaning or useful purpose, or whether they are not finely enough defined. One outcome is a set of intermediate classes, such as subkingdom, subphylum, superclass, subclass, infraclass, cohort, and tribe.

Three major strands of thought prevail in biological taxonomy: the phenetic, which considers physical characteristics only; the phyletic (cladistic), which considers evolutionary lineage only; and evolutionary taxonomy, which uses observed similarities and differences, as well as evolutionary history. Because knowledge of evolutionary descent is determined by meticulously examining all characteristics of form, such as the macrolevel of skeletal fossils or the microlevel of molecular biology, the reality is the phenetic and the phyletic tend toward convergence. If the fossil record for any group were complete and taxonomy completely established, phenetic and phyletic arrangements would be identical.^[11]

Chemistry and physics provide a well-known example of a classification, which is seldom labeled a taxonomy

but most certainly represents one: the periodic table of the elements, in which chemical elements are arranged in a highly structured format according to inherent properties. One measure of the validity and usefulness of the periodic table is its power to predict new elements, a function at which it excels. Another measure of its strength is its descriptive power. The taxonomy structure of the periodic table represents very detailed knowledge about any given element, and the ability to read the table enables one to learn much about elements and their relationships to each other.

As scientists extend human senses with ever more detailed examination of basic units of matter, such as DNA and subatomic particles, definition and classification of common taxonomic subjects continues to shift. A case in point is that of wolves, illustrating ongoing debate over defining a species.^[14]

Numerical Taxonomy

The advent of molecular biology—with modern research instruments and methodologies, massive numbers of data points, and corresponding quantities of data values—has prompted the development of new techniques for discerning similarities and differences in organisms. A strictly phenetic approach, numerical taxonomy (also known as taximetrics) is the application of multivariate analysis to measurable features. By using quantitative methods to manipulate large amounts of data and numbers of specimens, numerical taxonomy derives classes and populates them on the basis of inherent properties. Depending on the techniques used, numerical taxonomy either clusters organisms directly, on the basis of similarities (correlation) or indirectly by virtue of differences (distance). In cluster analysis, correlation and distance measures are the inverse of each other.

Many measures of correlation exist, but it is often computed using the Pearson product–moment correlation:

$$r = \frac{\sum (x_1 - m_x)(y_1 - m_y)}{(n-1)s_x s_y}$$

where

r is the product–moment correlation coefficient

x_1 and y_1 are the x and y values for one member of a population

m_x and m_y are the mean of x and y , respectively

s_1 and s_2 are the standard deviations of x and y , respectively

n is the number of measurements

The value of r varies from -1 to 1 , with the strength of correlation expressed by the distance from 0 , giving an r value for either positive or negative correlations. Assuming two variables with normal distribution, r is a reasonable correlation measure to use. If the distributions deviate widely from normal, or the sample is not large, other

correlation measures are more appropriate.^[15] Because the correlation and distance measures are inverse, one might think that measuring dissimilarity would simply involve taking the inverse of r . Although that is possible, a more direct approach is to compute the Euclidean, or Pythagorean distance, d , between pairs of values. The equation is expressed in many forms:^[16]

$$d = \sqrt{((x_1 - x_2)^2 + (y_1 - y_2)^2 + \cdots + (x_{1n} - y_{1n})^2)}$$

where

x_1 and x_2 are the x and y values for one member of a population

y_1 and y_2 are the x and y values for another member

n is the number of measurements

For the purposes of numerical taxonomy, strong correlations (or, correspondingly small distances) are taken as indications of similarity.

Numerical taxonomy is not without criticism. It has not been adequately considered whether the mathematical and statistical techniques involved are appropriate for taxonomy.^[11] Furthermore, there is some risk of selecting irrelevant observations as variables; a trivial example would be to calculate r for species and habitat (to say several organisms are similar because they live in the same vicinity would be erroneous).^[12] A more serious risk is that of grouping things based on the absence of a particular feature (many men are balding, and balding is a genetic trait; nevertheless, not all balding men are related).

Contemporary Taxonomy

It is no longer possible to think of taxonomy as process and practice and taxonomies as products in two or three closely related senses only; the terms have acquired a variety of widely disparate meanings, depending on discipline, domain, and application. Interest in and practice of taxonomy has exploded in the early years of the twenty-first century, with Google Scholar returning over 880,000 search results for “taxonomy” in free text and over 825,000 in the title in mid-July, 2008. Noteworthy is the large proportion of results categorized as from the domain of social sciences, arts, and humanities, 16%; and 11.5% from engineering, computer science, and mathematics. Considering that information science overlaps the two categories, it seems reasonable to posit that taxonomy has recently attained considerable status as a research topic outside its traditional sphere of the natural sciences (46.5%). Thus, the proper field of discussion is classifications that have taxonomic characteristics, known as taxonomic classificatory structures, or simply, taxonomic structures. Such constructs can describe abstract concepts, such as opinions, thoughts, behaviors, intentions, emotions, ideals, mores, and beliefs, as well as physical objects that exist independently of human thought.

Whether abstract concepts can have inherent and immutable properties is open to debate. Nevertheless, organization of them seems amenable to certain taxonomic principles, and useful classifications are possible. In this entry, taxonomies and taxonomic structures are used somewhat interchangeably, although taxonomy often refers to process and practice, as well.

Many disciplines, such as biology, physics, astronomy, psychology, and linguistics, generate taxonomies of a classical nature and use them primarily for descriptive purposes. In some cases, classifications are used as research instruments, in which their predictive powers provide a means for testing hypotheses. A different application is the use of taxonomic structures for their ability to affect, wholly or in part, computer and information operations: artificial intelligence (AI), information science, and object-oriented programming (OOP). Artificial intelligence and information science both construct taxonomic structures to deal with massive amounts of information, whereas OOP uses them as integral parts of its methodology and computer programs.

Ontologies in AI

Taxonomic structures in AI are more commonly known as ontologies. Because AI draws heavily from deductive logic, which depends heavily on assertions and facts, AI developers compile facts and data about the objects within particular domains of interest. These compilations are called knowledge bases, and ontologies are an essential tool for managing them. As used in AI, an ontology is more closely akin to kinds of abstract entities to be admitted to a language system. Such concepts are organized generally in a manner that permits sharing and reuse.^[17] Ontology and taxonomy often have the same sense: a classification of categories or kinds of concepts, maintained in a knowledge base.^[18] In AI, the term ontology has several senses. Some researchers in the AI community consider an ontology to be an abstraction, without realization in concrete form—the conceptual and logical mental construct that forms the basis of a knowledge base—the design, which may be either explicitly formalized or implicitly assumed. Others consider an ontology to be some explicit terminological or semantic structure that captures and expresses the abstract logical design.^[18] It is the latter sense that more closely fits the notion of taxonomic structures.

Object-oriented programming

An object-oriented program has many of the characteristics of a taxonomic structure. Essential to OOP are the notions of class and inheritance, both essential components of a taxonomy. Class, in OOP, refers to the concepts of object type (which enables reuse based on type) and modular program structures. For the purposes of understanding an object-oriented program as a taxonomic

structure, classes can be thought of as software concepts that are instantiated with programming objects. Classes (thus, objects) have degrees of similarity and dissimilarity, characteristics that enable relating them to each other in hierarchical structures. Because computers require explicit instructions to function, OOP has developed very explicit rules for construction of classes and development of inheritance. Classes may be variants of other classes; a subclass will have all the properties and methods of its superclass, plus some additional characteristic, and they may be combinations of other classes, again with all the features of their ancestors; the intersection of features sets them apart from their ancestors. It is the two qualities of defining program elements in terms of other elements and relationships (particularly hierarchical ones) between the elements that define object-oriented programs as taxonomic structures.

Information access systems

Although taxonomic structures of several types have been essential components of information access systems for many years, the rapid growth and development of the World Wide Web, as well as various intranets that use technologies developed for the Web, have prompted renewed research and development. Indeed, as the distribution of Google Scholar search results for the social sciences, arts, and humanities topic area (19%), plus engineering, computer science, and mathematics (14%) indicates, the information industry has fueled the expansion of taxonomy more than any other factor. At the opening of the 1990s, taxonomy, with few exceptions, meant the descriptive arrangement of organisms and objects in the natural sciences. Scholars often developed small, very limited, highly specialized taxonomies as instruments for research in psychology and the social sciences. The principles of taxonomy were also receiving close scrutiny by computer scientists in AI and OOP. That was the extent of interest in taxonomy. By the end of the twentieth century, however, taxonomy had become a phrase to describe almost any information access system that attempted to match an information user's terminology with the terminology in a system. Given almost another decade, the label "taxonomy" has been applied to such wide variety of language and terminology compilations as to severely dilute the original meaning of the term in common parlance. "Taxonomic structure" represents an attempt to more systematically define the discipline. Exponential growth in the volume of information on both the Web and various intranets has highlighted the need for such terminology control.^[27]

Researchers and practitioners continue pursuing taxonomic structures as a means of providing useful and reasonably sized search results from Internet catalogs containing several million sites. The explosion of information available over the Internet and private intranets has exceeded the ability of simple keyword searches to

retrieve information; as a result many sites have turned to classification schemes, often called taxonomies, to help users find information.^[28] Some system builders use techniques from natural language processing (NLP) to generate classification of key words and phrases from text. These classifications can be combined into a single, virtual taxonomy for retrieving information from the Web. The primary purpose of these taxonomies is to resolve ambiguity and duplication in language.^[19] Although many of these classifications are not taxonomies by classical definition (especially internal ones for nonpublic use), research and development continue in the theory and practice of constructing effective taxonomic structures. At the same time, development and use of more traditional taxonomic structures continues. The following systems are particularly important, being almost alone among taxonomic structures in information access systems as having been developed according to widely accepted practices and standards: hierarchically arranged subject heading lists (Library of Congress Subject Headings), geographic place names (Thesaurus of Geographic Names), traditional classifications (Library of Congress Classification and Dewey Decimal Classification), and various indexing languages and thesauri [Art and Architecture Thesaurus, INSPEC Thesaurus, (ERIC) Thesaurus of ERIC Descriptors, to name a few]. The accepted standards for developing thesauri and indexing languages are: Guidelines for the Construction, Format, and Management of Monolingual Thesauri, ANSI Standard Z39.19-2003; Guidelines for the Establishment and Development of Monolingual Thesauri, ISO 2788; Guidelines for the Establishment and Development of Multilingual Thesauri, ISO 5964; Guidelines for the Establishment and Development of Monolingual Thesauri, BS 5723; and Guidelines for the Establishment and Development of Multilingual Thesauri, BS 6723.

THEORY AND PRINCIPLES OF TAXONOMY

Taxonomy has legitimate roots in the natural sciences, logic, linguistics, semantics, and the cognitive sciences; collectively, these contribute to a body of theories and principles that provide rigorous guidance to the construction of taxonomies. Taxonomy is also pragmatic; a taxonomic structure must serve at least one useful purpose or be discarded, no matter how carefully and correctly constructed. Because of this dual nature, one must sometimes turn to the practice of taxonomy to discern theory and principles, and other times study theory and principles to establish practice, which is well illustrated in the earliest taxonomies. Aristotle established the practice of observing characteristics of form, habits, and habitats of plants and animals, using these properties to identify and define the organisms. In doing this, he also explicated certain principles and established an early theory of

taxonomy. Aristotle's categorization of organisms was well grounded in the philosophy of logic, particularly deduction. Theory posits as an axiom that organisms sharing certain characteristics are related to one another. In fact, if they share enough particular characteristics, they are separate instances (members) of the same category. Empirical observation notes that certain organisms share certain characteristics. Logic deduces the organisms are related. The circularity of this argument, based as it is on an accepted axiom, does not detract from utilitarian practicality of the resulting categories. Thus, theory and practice have collaborated to produce a useful outcome. To be correct, of course, the syllogistic argument must be logically correct (i.e., the axiom properties pair must entail the conclusion). In other words, the axiomatic properties must establish necessary and sufficient criteria for membership in the category. Therein lay the difficulty, unaddressed for many hundreds of years: how many and which properties are necessary and sufficient? Furthermore, what degree of difference or similarity must be present to class something in one class or another? Pragmatism states that utilitarian practicality is the final arbiter.

Hierarchically arranging structures of knowledge is another important principle and practice of taxonomy, sitting solidly in the pragmatic camp as a means of representing knowledge. Although organizing and categorizing things, information, and concepts are instinctive and practiced by all humans, arranging categories hierarchically seems to be a learned behavior and is possibly not practiced by all cultures. In Western tradition, hierarchical classification [i.e., representations which graphically display similar entities (in clusters) and dissimilar entities (as apart or separate from each other)] did not arise until the work of Andrea Cesalpino, with his *De plantis* (1583), a systematic taxonomy of plants. Empirical attention to inherent characteristics does not proceed for long without the observation that not only are some specimens more alike than others, but some groups of specimens are more alike than others. It makes sense to cluster groups and to cluster those clusters repeatedly until all clusters are gathered into one. This methodology, building ever-larger groups with a process of gathering like items together, did not prevail prior to Linnaeus. Until his time, the standard practice was a combination of empirical observation, which identified specimens as members of a species, and successive division of a large class into ever-smaller groups until suitable categories were found for the species. Often the intermediate groups were created by examining habitats (shore birds, alpine flowers, desert shrubs, etc.), modes of locomotion (wading birds), or function (hunting dogs, draft horses, aromatic plants, medicinal plants). In some cases, groupings created on the basis of observation of action (perching birds) coincided with orders defined on the basis of inherent properties (Passeriformes); but the overlap was accidental, not based on a rigorous principle of grouping organisms because of common inherent

structural qualities (e.g., the shape of certain birds' feet). Linnaeus applied the principle of inherent properties to the higher categories (taxa), which is still in use. Darwin considered evolutionary lineage as a characteristic to include when developing hierarchical categories. In this he introduced the new principle of developmental stages as a method of hierarchical arrangement. Although the use of evolutionary history applies, strictly speaking, only to biological organisms, the principle of arranging taxonomic structures according to lines of ancestry and descent has broader application. A common example is a genealogy or family tree. Other examples include a series of product lines, the history of inventions, and the growth of ideas; all of which are topics amenable to classifying with hierarchical taxonomic structures along evolutionary, or developmental lines.

With widespread adoption of these five principles of logical entailment, empirical observation, hierarchical arrangements based on similar inherent properties, evolutionary history (or developmental stages), and pragmatic utility, taxonomy has a solid foundation. Understanding gained in the twentieth century from linguistics, semantics, and cognitive psychology has added new theoretical principles and refined existing ones. The very strict requirements of programming computers for AI, NLP, OOP, and information access have renewed attention to understanding language and how the mind works. A significant contribution from linguistics is understanding of the relationships between words. Semantics focuses on the words used for labeling the concepts classified in taxonomic structures. From cognitive psychology comes awareness of how the mind organizes thoughts and processes language, especially for different purposes, such as determining relevance, generality, or subsumption. Purposes in classification are accomplished by using language, and evaluating terms for appropriate use seems to be driven by mental constructs, which may be called principles.^[20] The relationship between a concept and a lexical unit (lexeme) represents a binding function in language; various relationships connect thoughts, meaning, ideas, objects, anything about which communication is possible. Certain relationships are particularly important: generic (a.k.a. genus-species, kind-of, IsA or Is A), meronymy (partitive, or whole-part), genealogical (ancestor-descendent), membership, equivalence, association, causality, and temporal precedence. Many relationships are hierarchical in nature, but the associative relationship has received increased attention in recent years.^[21] The generic relationship, which is hierarchical, is equivalent to logical entailment: concept A, represented by term A, has all the characteristics necessary for concept B, represented by term B, to be a "kind of" A. In this the relationship is not only logical but also definitional (semantic). Definitions determine subsumption, which is similar to the logic involved in entailment. Entailment, or subsumption, may be used to test the equivalence of

definitions; the absence of equivalence can be interpreted as the presence of subsumption.^[22] The meaning of a concept, or lexeme, determines logical relationship among concepts and lexemes.

Careful attention must be given to the words used for labeling concepts in taxonomic structures, the "nomenclature." Classical taxonomy has developed rules for naming nodes at each level of a taxonomic tree. At the species level, for instance, plants and animals have a binomial name consisting of the genera and a differentia, a term setting one species apart from all others in the same genera. Indexing languages (thesauri) following standard guidelines cast most concept labels in the form of plural nouns, which reduces ambiguity in cases where the singular form could be any of several distinct lexemes, each with its own sense of meaning. For example, "map" without a definite article might be a verb or a noun. "Maps," isolated from a sentence, is more likely understood as a plural noun. In cases of nouns alone, having no possible confusion with verbs of the same form, the singular always refers to one of something, whereas the plural refers to many, which constitutes a class or group of things. Classes are the fundamental elements of classification and taxonomy. Use of the plural form reduces confusion as to whether the referent is a concept, or an instance or exemplar of the concept. Lexemes may be single, compound, or multiword. As compound and multiword terms, they frequently serve to subdivide classes of things. For example, the class of tools called *saws* may be divided into cross-cut saws, rip saws, and coping saws, or chain-saws, electric saws, and gas-driven saws, respectively. Clearly, the form of a lexeme serves to create an implicit placement in a hierarchical taxonomic structure.

The particular example of saws illustrates two principles of classification: by use or application (cutting across the grain, cutting with the grain, making small, curving cuts), and by inherent property (saws with teeth fastened to a chain, saws driven by electricity or power). Seemingly trivial in this example, classification by external attributes, such as activity, habitat, diet, clothing, or associations, has rationalized oppression for millennia. Taxonomy, poorly done, runs the risk of incompletely and inaccurately describing human experience, perception, and beliefs, with consequent detrimental outcomes.

Cognitive psychology provides insight into classification as mental process, giving strong support to incorporating hierarchy into taxonomic structures and establishing guidelines regarding terminology choice and form. Organizing perceptions, data, information, and thoughts is an important part of acquiring information, making sense of that information, and problem solving. With classification, people develop mental pictures of topics and problems, which may be divided and subdivided, thus simplifying the learning of complex knowledge. Classification is also useful for developing inferences or expectations directed at achieving specific goals. Classification and taxonomy

are fundamental components of learning, communication, and comprehension.^[3] The importance of hierarchy as a feature of taxonomic structures cannot be overstated. Several studies support the notion that hierarchical structures are a fundamental and essential component of memory.^[23] Word association tests elicit information, not only about the test words but also about the classes that contain them. Other studies indicate a mental transformation of nonhierarchical statements into hierarchical form, possibly in an effort to place new perceptions into some familiar context. Grouping of concepts that seem similar is thus a means of generalization and simplification.^[23] Taxonomic structures provide efficient storage mechanisms for data and information; if such structures accurately model internal mental constructs, they are more likely to be useful. Classification enables people to deal with categories and groups, rather than individual instances, thus enabling more efficient use of memory and cognitive processes.^[1]

- Information finding

Classification can mean either assigning entities to existing classes or creating classes by clustering existing entities. Taxonomy means both: classing entities and creating new classes. Collections of entities are examined to create a taxonomic structure and individual entities are assigned to the classes (taxa) created. Once the initial collection is classified, new specimens, or entities, are assigned to existing taxa; the structure is dynamic and, if necessary, new taxa may be created. An example of this is the recent creation of two biological superkingdoms to reflect fundamental differences in cell structure.

Discussion of taxonomy methodologies and uses may, itself, be organized into a simple taxonomy, illustrated here in an indented outline:

Methodologies

- Systematic
 - Manual
 - Automated
 - Numerical
 - Semiautomated

- Organic
- Uses
 - Descriptions
 - Abstract pattern visibility
 - Analysis
 - Visible patterns clarify further direction
 - Visible patterns expose gaps
 - Visible patterns expose overlaps
 - Predictions
 - Language maps
 - Structures
 - Hierarchical—existential relationships
 - Synonymy—semantic relationships of equivalence
 - Associative—situational and/or contextual relationships important to communities of interest and practice; e.g.:
 - Process—product
 - Geographic location—governing entity
 - Object—purpose
 - Event—unit of time
 - Information retrieval systems

Use of this outline to discuss methodologies, practices, and uses, will illustrate some of the power of taxonomy for organization and communication.

Systematic taxonomy follows, as one might expect, rigorous processes and policies, which have themselves been through several cycles of development, test, revision, and adoption; they have, in other words, withstood the tests of time and pragmatic utility. In manual taxonomy construction, a collection of elements is examined carefully, and inherent properties are listed. Through an iterative process, the properties, and thus the elements, are grouped into taxa of similar entities, which, in turn, are grouped into a hierarchy of increasing specialization. Automated taxonomy has a similar goal but attempts to attain it in different ways. In numerical taxonomy, mathematical techniques of cluster analysis are applied to listings of inherent characteristics. The same techniques are also applied in domains with inadequate inherent features. One solution is to use the technique of content analysis to evaluate data from various sources such as questionnaire responses, interviews, and usability studies. One school of practice attempts to extract taxonomies from text based on linguistic features: notably, word and phrase frequencies, cooccurrence, part-of-speech, and proximity. Many variations of this approach exist, but the basic theme is that literature about similar topics will use similar language, and such similarities can be discovered and revealed by using mathematical techniques. One of the variations involves a simple raw processing of text, accepting the results. Most efforts, however, “train” computer programs with manually constructed taxonomies and carefully selected corpora of text, a process in which the program “learns” which word and phrase patterns are significant within chosen design criteria. The program is then used to

analyze a much larger body of text. In many respects, this procedure is only the classing, or indexing, half of the taxonomy process; it makes no pretense of generating taxonomic structures from scratch. A semiautomated process would be that in which mathematical techniques generate a suggested taxonomy, which is then subjected to a manual review and edit process, producing the final taxonomic structure.

Organic taxonomy, in the form of “folksonomies,” and other “social” phenomenon, represent the human desire for involvement and autonomy in the very fundamental acts of sense-making and communicating as simultaneous social and individual behaviors. Folksonomies and other shared tags created by end-users, rather than authors or professional intermediaries, have received a great deal of attention in recent years.^[24–26] Although they do not represent formal taxonomy, they serve similar pragmatic purposes and address some of the issues plaguing taxonomy; notably the problems of scale, complex rule sets, and arriving at consensus for agreement about language. Noteworthy characteristics of folksonomies include: flat lists of terms (keywords), multiple meanings for identical terms (homography), and multiple terms for one concept (synonymy). At best, the three features alone maintain the ambiguity inherent in natural language (particularly when out of context). At worst, they increase ambiguity. Folksonomies by themselves do little to facilitate agreement about meaning, nor do they serve well as classifications. Without reasonably disciplined and systematic attention to the principles and practices of taxonomy, folksonomies are informal categories at best.^[25] Nonetheless, folksonomies provide valuable insight into the thinking, behaviors, needs and desires, and properties of many more people and information entities than might otherwise be possible. They offer potential as useful additions to the taxonomy toolbox.

In the absence of reasonably defined and desired purposes, taxonomy has little value other than satisfying individual interests and motivations. More communal uses include description, analysis, prediction, language agreement, and retrieving information, as outlined above.

At its most basic, taxonomy has descriptive power; if any given taxonomy, particularly its structure, does not describe the covered domain, identification of it as a taxonomy comes into question. At best, the structure might be a collection of loosely related categories. Description sets baselines, provides foundations, creates common starting points for extending taxonomy to other purposes. Following description, taxonomy facilitates information and knowledge analysis. It reveals patterns which help clarify possible future actions; it exposes gaps and overlaps in representations of knowledge. Such exposures, in turn, identify other possible actions. Highly structured and richly detailed taxonomic structures, such as the periodic table of the elements and evolutionary trees, predict the existence of yet-undiscovered elements and prehistoric organisms.

In information science, taxonomy performs the very useful function of mapping language. When integrated into information systems, particularly for browse and search, taxonomic structures serve many purposes, all working together toward both high recall and accurate precision, an elusive goal for many decades. Simply listed, taxonomy functions in information systems to

- Represent communally accepted language.
- Promote shared use of language.
- Provide clear paths into detailed levels of specificity.
- Enable aggregated retrieval of selected specific concepts using a broader collective label.
- Convert end-user search terminology to that developed by communities of practice.
- Use that terminology for search, both metadata enabled and free-text.
- Suggest related avenues of exploration and search.
- Programmatically deliver information of possible interest to select individuals and communities based on inherent and situational characteristics of them.
- Facilitate reporting and analysis of end-users, content, content creators and providers, and storage and delivery systems.
- Enforce regulatory compliance.

This list does not exhaust the possibilities. In short, taxonomy connects the dots, closes the loops, and provides the linguistic and semantic backbones necessary to complete information transactions.

After years of research and development, integration of taxonomy with information systems has still not expanded much beyond relatively small academic pilots and applications in private industry or large government agencies. Obstacles to adoption include scalability, funding, and, often, misunderstanding regarding the value of such systems.

SUMMARY AND CONCLUSION

From its beginning as a process and system for organizing plants and animals, taxonomy has developed into a widely varied collection of classification schemes and practices applied in many disparate disciplines. In various natural sciences, particularly biology, astronomy, and geology, taxonomy continues as an important practice within each discipline. In the twentieth century, new techniques using statistical analysis and computers came into use for classifying natural objects and organisms on the basis of inherent properties that were previously unavailable for study. This is particularly the case in microbiology where numerical taxonomy creates clusters of organisms having similar genetic properties. Numerical taxonomy has also been applied in the social sciences and information access applications, although the

validity of the clusterings as accurate representations on inherent similarities in those disciplines is open to question. Taxonomies are an important part of systems developed for exploring AI. There, they take the form of ontologies, highly structured compilations of data, information, and knowledge that are used to support the logical reasoning attempted by AI. The computer science practice of OOP also incorporates taxonomy in the sense that object-oriented programs can be categorized as taxonomies. They have the features of class and inheritance, which correspond to the taxonomic features of taxa and relationships of entailment, expressed in hierarchical structures. Information access systems utilize taxonomies for navigation of Web sites and to aid searching for information on the Internet. In the context of electronic online information, taxonomies support retrieval of as many relevant information items as possible and retrieval of highly specific items. An essential contribution of taxonomy to such systems is their ability to disambiguate terminology by representing the relationships between concepts and thus providing context in which to understand and use domain-specific vocabularies. Having begun in the study of biology, taxonomy has developed a solid structure of theory and principles that guide methodology and development of taxonomic structures, with application and use far removed from taxonomy.

Beginning with the collection and study of inherent characteristics of many members of a domain of interest, taxonomy uses principles of logic and linguistic entailment, semantics, and meaning, plus insight into human mental activity to create taxonomic structures with practical utility. Regardless of where practices or with what final purpose, taxonomy utilizes of the common methodology of examining many specimens of examples of things to be classified into a taxonomic structure. Such examination may be manual, automated, or semiautomated. Each emphasizes different principles of taxonomy theory, with manual being the most comprehensive and semiautomated attempting to use automation to handle large amounts of data needing human interpretation. Automated methods include clustering algorithms and various techniques from NLP.

Regardless of the methodology and techniques used to develop taxonomic structures, in the final analysis, they are utilitarian objects, whether they serve academic research and descriptive purposes or more commonplace information retrieval from the Internet and other information systems. Well-designed and constructed taxonomic structures have descriptive, predictive, and analytical powers, which make them essential components of many information science endeavors. Integrating taxonomy with information systems can enhance end-user experiences and retrieval of desired information in many ways, all part of a chain of transactions, characterized as “connecting the dots.”

Technical Writing

Michael J. Salvo

Department of English, Purdue University, West Lafayette, Indiana, U.S.A.

Abstract

Technical writing conveys practical information for readers to put to use. Technical writing is done in most workplaces by a variety of professionals whose interest in writing is secondary to their primary work function, while specialists in technical communication concentrate on the processes of effective writing and knowledge creation. Professional and technical writers research and articulate solutions for professionals who need to write effectively. Therefore, technical writers construct and manage others' writing environments, and are responsible for managing documents, knowledge, and information flow in organizations. Technical writing is writing with a purpose in an organization, and so is distinguished from creative writing and academic writing in its purpose, scope, and audience.

INTRODUCTION

Defined narrowly, technical writing articulates process, procedural, and practical information both for specialized and general audiences. Technical writers interpret complex technical concepts and articulate ideas in accessible language to enable users to accomplish their goals. To present appropriate content, writers must understand the audience who will use the document and their purpose in using it. Audience analysis is a key feature of technical writing. Technical writing is writing with a specific purpose, intended to convey information from producer to consumer in the clearest and most effective way possible. Technical writers work with a variety of genres: they inform their organizations by preparing whitepapers and research reports, support decision-making with recommendation reports, and support organizational knowledge by writing procedural manuals, writing and maintaining policy, and managing collections of internal documentation. Common forms of technical writing include procedure guides and how-to manuals for household appliances and electronics. As an academic field of study, technical writing expanded in the late twentieth century as personal computers became ubiquitous and Internet connections common. Indeed, as computers moved from desktop publishing to network communication devices, digital Web-based new media have redefined the boundaries of a field once limited to written communication. In the late twentieth century, technical writing grew to include a wide variety of communication media, and hence expanded to the more expansive moniker of technical communication. Today, technical communicators work under a variety of professional titles. The list, of course, includes technical writer, but new titles are as varied as copywriter, content manager, user-experience designer, information architect, information designer, and document manager. Technical communication specialists continue

to advise organizations on effective communication practices.

The rise of technical and professional writing in America is closely tied to the development of the Morrill Land Grant Colleges in the twentieth century. Indeed, the location of these programs, their names, and specialties are very much a product of local conditions and traditions. Technical writing is most closely tied with a tradition of nonacademic writing that supported writing instruction for engineers and scientists. Professional and business writing often accompany writing instruction in business schools. Recently, more programs have taken on the name technical communication to reflect the expanded role in speech and multimedia presentation. In the middle to late twentieth century, the growth and expansion of technical communication as a field in its own right is closely tied to the expansion of personal computing technology and, at the turn of the millennium, the growth in popular use of the World Wide Web. Recent interests in information design and information architecture closely link the research being produced in technical communication programs to the research being undertaken by researchers in library and information science, creating opportunities for collaboration and hybridization between the two fields. Technical writing is complex, dynamic, and expanding, technologically sophisticated, and concerned with the role of users in producing, accessing, storing, retrieving, and perhaps most importantly, understanding and putting to use the information stored in texts written to support high technology. Both technical communication and information science share an interest in innovation and expansion into the growing culture of new media and the storage and retrieval of human knowledge through the World Wide Web. There are analogous, if sometimes competing, definitions of technical writing, often quibbling over the scope of the term and asserting differences: that professional communication contains technical and business writing

rather than technical communication serving as the larger term. Such taxonomic distinctions are important to specialists in the field, often revealing institutional as well as historical lineage as well as political and cultural sympathies of various departments and programs within higher education. Technical writers emerge from the study of rhetoric and rhetorical theory, and technical writing provides the nonacademic counterpoint to the large field of academic writing often called composition, which focuses on the first year as well as upper-level academic writing in postsecondary institutions of higher learning. Rhetoric and writing programs are gaining recognition, and increasingly are being titled “writing studies.” This entry discusses the long history of technical writing with particular attention to the post-World War II era through the late twentieth century. The late twentieth and early twenty-first century development of technical writing is closely associated with personal computing and the World Wide Web, and the entry concludes with discussion of emerging digital media, with special attention to developments in information design and architecture.

RECENT RESEARCH

Recent research in technical writing has moved beyond the 1990s concern with professional recognition and legitimation. The field’s preoccupation with its own status is exemplified, and seems to have concluded, with publication of the two-volume collection *Power and Legitimacy in Technical Communication* edited by Teresa Kynell-Hunt and Gerald Savage.^[1,2] Recently, activity theory has emerged as a viable foundation for grounding technical writing research, exemplified by Clay Spinuzzi’s 2003 *Tracing Genres Through Organizations*.^[3] Spinuzzi’s book historicizes genre, encourages teachers to include history and rhetoric in technical writing pedagogy, and connects present research to the constructivist tradition, such as Joann Yates’ *Control Through Communication*,^[4] an example of cultural history tracing the development of business and technical writing through the nineteenth century. Recent books, such as the edited collection *Critical Power Tools*,^[5] have articulated the relationship between technical writing and cultural studies and the role of new media, as with Carol Lipson and Michael Day’s *Technical Communication and the World Wide Web*.^[6] Methodology in technical writing research has been a perennial concern; emerging from a humanities perspective, scientific methods have sometimes been mismatched with the goals of technical writing. Some of this uneasiness seems inevitable as technical writers often represent the needs of non-specialists to scientists and engineers. The history of rhetoric is older than that of scientific inquiry, and measuring effective communication in context is a qualitative rather than quantitative endeavor. In response, some researchers have used rhetoric’s uneasy relationship with

empirical methodology as a strength, opening spaces for critical, reflective research.^[7] Johndan Johnson-Eilola and Stuart Selber’s *Central Readings in Technical Communication*^[8] collect landmark essays in the twentieth century while also asserting the centrality of journal articles to the development of the field: the development of technical communication research has been driven by articles in a healthy number of scholarly and professional journals such as (alphabetically listed) *Business Communication Quarterly*; *IEEE Transactions on Professional Communication*; *Information Design Journal (Document Design recently merged with IDJ)*; *Journal of Business Communication*; *Journal of Business and Technical Communication*; *Journal Of Computer-Mediated Communication*; *Journal of Computer-Supported Cooperative Work*; *Journal of Technical Writing and Communication*, *Kairos: A Journal of Rhetoric, Technology, and Pedagogy*; *Management Communication Quarterly*; *Written Communication*; *Technical Communication*; and *Technical Communication Quarterly*. Technical writing research has for the most part left concerns of the field’s legitimacy behind in the late twentieth century^[1,2] and much recent research has been articulating what Bruno Latour^[9] calls the parliament of people, texts, and technology.

TECHNICAL WRITING AS A FIELD OF STUDY

Technical writing as a profession was boosted in the late twentieth century with the widespread adoption of personal computing technology in the workplace and for home use. There was a need, within the hardware producers and programming organizations, as well as among independent writers, to clearly document and guide growing numbers of users through the process of effectively utilizing digital computers on the job and in the home. In the early twenty-first century, as more documentation is available online, there is less need for print-based documentation separate from the program as many new applications integrate guidance within the programs themselves.

Technical writing can no longer, if it could ever accurately, be defined simply in functional terms or limited to the scientific need to write with clarity, brevity, and specificity. This is, in the early twenty-first century, considered a limited and antagonistic definition (referred to as the “CBS” school) that arises out of a history of technical writing’s uneasy placement within the humanities. In higher education institutions, most often located in departments of English, technical writing was often discounted as service primarily presented to programs in engineering and business schools. English departments eschewed their service roles in preference for literary study through the twentieth century. Late in the twentieth century and continuing to the present, growing numbers of writing programs are emerging with concentrations in both academic

writing, or composition, and nonacademic writing. While technical communication is predominantly taught in English departments located in colleges of humanities, specialized programs exist in engineering and business as well as journalism schools in addition to dedicated rhetoric and writing studies programs.

The rapid expansion of technical writing in the late twentieth century to meet the demand for documentation of personal computers created opportunities for writers without formal training in technical writing. Practitioners of technical writing have a wide range of training and experience, and with writing programs offering more and better workplace and professional writing curricula, researchers have noted generational tensions in the workplace between those professionals with coursework in rhetoric, project management, and usability and those with more traditional English coursework.

Early History

Earl Morrogh^[10] takes a long view of the history of technical writing, tracing its emergence as prior to and part of the inspiration for written literacy. Opening with clay tablets to the emergence of the alphabet to Roman military texts, this perspective is consistent with mid-twentieth century scholars' attention to literate representations for specific commercial purposes. Walter Ong^[11,12] traces the emergence of literacy back to cuneiform clay tablets used to account for trade in the eastern Mediterranean. These prealphabetic texts were technical in nature, counting the numbers of vessels of goods held in the holds of ships plying the calm waters of the ancient Mediterranean sea before even the Egyptians were building pyramids. These earliest texts were technical in their functional interest and attempt to record wealth, trade value, and to account for decisions made in foreign ports by agents of newly centralizing power. That is to say, technical communication is synonymous with the invention of centralized human society and cocreative of the modern human mind. Ong asserts that the Semitic alphabet was the first of its kind, replacing both the cuneiform tablet writing and pictographic representation of the Egyptians and that all subsequent alphabets are at least inspired by if not derived directly from the ancient Hebrew.

Similarly, Earl Morrogh asserts a very long lineage for what he titles information architecture, which he defines broadly as the struggle "to create, communicate, manage, and preserve information" (p. 3).^[10] Following Morrogh, technical communicators often define themselves in terms of the first two elements of the definition: creation and communication of information, while library and information scientists are concerned with the second two elements, management and preservation of information that others have authored. In the age of computers, ubiquitous access, and information overload, both technical communicators and library and information scientists find

themselves concerned with effective information storage and retrieval. Morrogh narrates a number of moments in the long history of human development in which information production outstripped contemporary technologies for storage and retrieval, and our current age of Information Anxiety^[13] is only the latest in a long series of epochal change: from speech to text to print, and the technologization of the word from telegraph, telephone, radio, and television, to our own information age augmented by the World Wide Web. Information architecture, then, is the field of inquiry where technical communicators and library and information scientists find their interests most closely aligned.

From Roman military manuals to the mining books of secrets written by Agricola, powerful and valuable technical knowledge was stored in written form. These texts, as described by Bernadette Longo,^[14] were both powerful and valuable, and as such were often written in code or the information was purposely misrepresented in order to keep the uninitiated in ignorance. Often, these how-to texts were both encoded and contained misleading information: acting as mnemonic devices, the books of secrets would unlock the magic of metallurgy, or of medicine, or of civil administration only if one had a guide to the books. These manuals were not intended for everyone: they were reminders to the initiated—memory books—and instruction manuals for the aspiring metallurgist, civil servant, or soldier, and reading would be accompanied by a learned guide during the period of apprenticeship.

The nineteenth century rise of mass culture and urbanization was accompanied by the rise of the corporation and genres of business communication that we recognize today. Memos, reports for decision-making, research and technology, and technical illustrations, as well as patent applications became common forms of intra- and interorganization communication. This is also roughly when card catalogs and written collection inventories, which become library holding databases, become common elements of both corporate and public library collections, information storage and retrieval processes that became part and representative of industrial age information storage and retrieval from the civil war through World War I.^[4]

Twentieth Century

Robert R. Johnson^[15] and Robert Connors^[16] locate the next major turning point in technical communication at the massive scientific and administrative expansion necessary to administer the movement of people and equipment in World War II. Accompanying the administrative and material challenges were the increasingly technical weapons and tools employed around the globe, from radar to mobile weapons and, in the increasingly swift processes of recursive design, upgrades to these systems on the battlefield. It became necessary to document new designs—improvements—so that soldiers in the field could, with

their existing literacy skills, open a weapon's packing crate, read the instructions, and successfully assemble and deploy new weapons. Robert R. Johnson reports that the first attempts at such user-centered design were disasters, resulting in mechanical malfunction, misfires, and bodily injury and even occasionally in an operator's death. Often these so-called accidents were attributed to operator (human) error; however, on closer reflection, it appears that there were, in the words of Donald Norman,^[17] "Gulfs of Evaluation and of Execution between the designer and user of the technologies." To solve this problem with human error (and the dangers of industrial accidents), designers had to consider the design not from their own but from the users' perspectives. Technology could be designed not merely for esthetic or functional ends but for easier, safer operation and the design of technologies could aid in their ease of use and adoption into the users' working lives. This realization leads, in Johnson's argument, to the rise of *user-centered design*.

After World War II, accompanying the expansion of need for technical expertise among soldiers on the line was the massive rise in technical consumer goods purchased for use in the increasingly popular suburban tract house. Everything from washing machines to refrigerators to, later, televisions were finding their way into the living rooms, garages, utility rooms, and basements of these single-family, lower-density houses. Lower-density neighborhoods encouraged greater reliance on automobiles. Automobiles required technical manuals to support regular maintenance, as America became a mobile, suburban culture in the middle twentieth century. These developments also resulted in expanding the vision of technical communication to include household technologies, as Katherine Durak^[18] argued, asserting "the household as a setting of consequence." From Agricola's books of mining secrets to the post-World War II suburbanization of American culture, technical communication has participated and expanded upon the spread of literacy to an increasingly high percentage of people, beginning with the preliterate need for accuracy in trade, expanded through the advent of the printing press, providing for the informational needs of an increasingly technological culture. Technical communication followed need into technical and engineering universities, exemplified by American land grant public institutions of higher learning, and into suburban homes with the adoption of domestic technologies from sewing and washing machines to refrigerators and later entertainment devices like radios and televisions. At the end of the twentieth century, technical communication became increasingly user-centered as the personal computer required precise task-oriented documentation and guidance. Online, the Web has many guides and documents showing how users can put their technological investments to better use. The widespread use of these many kinds of texts supported the dissemination and spread of the technological information these documents

contained, paving the way from what some critics have called a democratization of technology.^[19]

The postwar period of industrial expansion chugged along, building wealth and expanding the cold-war period of Pax-Americana, leading to the multiplication of access and complexity resulting in the dawn of the information age as exemplified first by the early adoption of personal computers in the form of hobbyists followed by the more robust and culturally significant spread of computer use with the commercialization of the World Wide Web (Web) and electronic mail. Personal computing further lowered the obstacles to the tools of printing and dissemination of texts. Even before the Web, do-it-yourself desktop publishing made it possible to produce many paper copies of documents. Document design^[20] became a concern of writers, further lowering the financial barriers to disseminating printed work. With the growth of personal computing, the need for clear, end-user-centered documentation increased, and programmers could no longer assume that their user had a similar level of technical preparation. Especially with the move from computer operating systems that ran on command line interfaces (CLI) to graphic user interfaces (GUI), many more citizens were able to purchase and put to use respectably powered computing devices in their homes and offices. And all this was possible before the advent of the Web.

Through the late 1990s, the Web created a cottage industry of secondary market how-to books for personal computing. Even before the Web, many technical writers found a thriving market in teaching new users how to take advantage of productivity software, digital tax and financial tools, databases, and word processing and desktop publishing applications. Bookstores reflected this expanding need for documentation that was better than the manuals produced by large programming organizations, eventually resulting in the humorously titled "Dummies" and "Idiots" guides to just about everything. These books are the result of the realization that we are a nation of experts who have deep expertise in a very narrow set of specialized knowledge. For the vast majority of high-technology situations, we are novices, or in the unfortunate construction of these books, we are geniuses in our specialties but idiots and dummies in everything else.

Understanding the user as human being is at the heart of user-centered and human-centered design that works to present a technology interface that effectively presents the power of the technology to the user, in a human scale and task-oriented perspective. Users need not understand the underlying technology represented by the interface but rather see how the tool lying behind the interface can fulfill their needs. Indeed, the interface is the face the tool presents to users. The shift from system to user-centered recognizes the widespread dissemination of high-technology digital tools throughout culture, the democratization of access in which all have a printing press, radio, and television receiver as well as broadcast

capability, and the PC moved from being seen primarily as a personal *computing* device and becomes a personal *communication* device. Technical writers filled a need by documenting and presenting information for effectively using these communication devices by people who had no interest in knowing how or why the technology works.

The New Millennium

The shift from computing to communication is a shift from, in Richard Lanham's^[21] words, looking at technology to looking through technology. For many, their personal computers have become their promised video phones, and although the travel is virtual, they are likewise personal transporters, allowing users to transport their vision, their gaze, across the globe and, through NASA's rovers and telescopic devices—our virtual eyes—out into space and to the very edges of the solar system.

The cost of entry was vastly reduced: no longer was it necessary to train—to become expert—in the use of computers. What followed was the need to increasingly redesign the interface and the procedures to get online and participate on the Web so that the greatest number of users could become self-sufficient online, getting connected to the internet at speeds that made new online media viable. YouTube is the latest example of an organization that learned how to better deliver video. By creating generally understood accessible standards for video upload, conversion, and distribution, almost all Web users have access to acceptable quality video—if users can access youtube.com, they have access to content. In this way, YouTube is a victory for participation and access, even if the content leaves many scratching their heads and wondering what value the content may have to culture. In sum, users get to participate in the creation of Web content and also access what has been posted, without regard for the meaning or value of what has been posted. Users accessing YouTube are not thinking about search algorithms, taxonomic structures, or about how the videos are encoded and made available online. However, each of these elements is of importance to the new generation of technical communicators who take very seriously design, placement, and accessibility of digital video: the very things that make YouTube an enjoyable rather than frustrating experience.

Accompanying the expansion of access for posting and viewing is an expansion to access to the organization of content. So-called folksonomies, which are augmenting more centrally controlled taxonomies, represent a new level of user-participation, actually labeling content with searchable metadata, so that users become organizers and archivists as well as end-users. This control not just of the content but of the organization and navigability of content—or its findability, to borrow a phrase from Peter Morville—is a hallmark of what has been called the second wave of internet entrepreneurship, commonly referred

to as Web 2.0. Folksonomies may seem to challenge the accustomed control and authority of the information organization professionals: that is, of information and library scientists. And perhaps from certain perspectives, it does. However, opportunities exist to invent, support, and change with evermore creative means of opening information up to user labeling and organization. Recent books like *The Wisdom of Crowds*,^[22] *Glut*,^[23] and *Everything is Miscellaneous*^[24] all assert a new and interesting role of information and library science, but this role is different from traditional librarianship, and shares much in common with recent research in technical writing.

Brenton Faber^[25,26] argues that “change” is both a powerful trope and new constant in the information organization. Libraries, traditionally described as beginning in the United States with Benjamin Franklin's subscription group through Carnegie-funded public lending libraries, have traditionally been seen as a site for access to printed material. However, just as railroads and shipping companies had to rethink their identities at the dawn of the information age, so too do libraries find themselves rethinking identities and embracing change, seeing themselves not strictly as providers of access to books. Rather, libraries are redefining themselves as providers of access to information, which also requires developing a critical sense of information valuation, so that library patrons can become increasingly effective users of information resources. However, the Internet age has given individual users much greater access to information. Likewise, librarians and information science professionals are encountering similar change and some have begun to reimagine their profession and responsibilities in terms of teaching library patrons effective and critical information assessment and retrieval, both online and in print. It is also ripe for deeper collaboration with technical writing as well as with closely and further flung specialties. Culture is and will continue to reconsider the definition of deeply held values, such as literacy, and information professionals are well-placed to not only participate but to create innovative practices in collaboration with professionals in related fields, like technical writers who also see the challenges of information architecture and user-integration as central to the challenges of this current wave of technological and cultural change.

This current age of change, seen from the perspective of technical writing and communication, has to do with the changing nature of expertise. Experts are expected to help guide nonexperts, what this entry refers to as end-users, or simply users, to accomplish what they want. Balanced with the challenges of user-centered design is awareness of experts, or stakeholders, who have responsibilities to the local institution, the national and international standards of professional conduct, and to historical identity. The rise of do-it-yourself culture is exemplified by the hobbyist programmer, seen as an information

seeker who challenges traditional modes of patron behavior in the library. Effectively preparing for Web-savvy internet users further complicates librarianship. Like librarians rethinking their role in an age of information, technical writers are redefining their professional responsibilities to take advantage of opportunities made possible with digitization of information, like findability, critical information assessment, and user-centered design. These skills are needed *in addition to* traditional professional responsibilities. And it is no easy task to develop whole new arenas of expertise and responsibility.

Jay David Bolter and David Grusin,^[27] writing about new media, coined the term *remediation* to describe the process of new media's impact on old. Radio impacted fictional novels. Television changes radio. And all have been affected by the massive and incredibly fast adoption of digital computing technology—specifically the worldwide expansion of use of the Web. It is important, as Bolter and Grusin explain, to remember that radio didn't simply disappear when NBC, CBS, and ABC started broadcasting. So too, the three networks didn't cease their broadcasts when cable became another common way of accessing televisual media. Mentioned above, railroad executives—or managers of old transportation media—who saw themselves as operating engines and cars on rails, soon found themselves at a distinct professional and cultural disadvantage to those visionaries who saw trains as part of a network that transported goods around the world. These postindustrial workers engineered better systems for transporting these manufactured goods and raw materials between cargo ships, trains, and trucks—an arm of business management now known as logistics—found themselves in widespread demand and valuable members of the team of symbolic analysts who support the postindustrial global economy. So too, technical writers who see their profession in limited ways as creating static documents for packaged software systems with long development lives and slow redesign cycles have witnessed reduced opportunity and less prestige, while those who have ventured into Web-based delivery, experimented with new software models like open source and usable systems, have found themselves in increasing demand for their expertise. As Faber argues, change has become the one constant.

FUTURE OF TECHNICAL WRITING

Technical writing sees one of its future directions of growth and development in information architecture, of creating structures users can participate in and better take advantage of greater access to information resources. Technical communicators see information scientists and librarians as potential partners rather than rivals with whom the future of information architecture and design can be invented and communicated. Whereas technical

communicators emphasize the creation of content, effective writing and reading, and writing texts that help readers comprehend and put information to use, information science professionals emphasize storage and retrieval of that information. Opportunities for hybridization, cross-fertilization, and cooperation in understanding and innovating in an era of great technological and cultural change exist. Technical writers look towards a future integrating processes of information design and information architecture into their traditional roles of writing effectively to be read, as information scientists learn how to better support the challenges of user-initiated search, and accommodate the expansion of access to information through the Web, as the definition of librarian changes to include emerging responsibilities of information scientists.

CONCLUSION

In the early twenty-first century, technical writing is in a state of transition and flux. Like so many professions with roots in the expansion of industrial post-World War II American culture, technical writing is struggling to rearticulate its expertise in the postindustrial, global, and digital age of information. Research in the field of rhetoric and writing studies has articulated numerous directions for technical writing to take in its twenty-first century redesign. Most promising among these are information design and architecture, which rearticulates technical writing expertise in terms of Robert Reich's symbolic analytical work, redefining work as symbolic manipulation, a definition much in synch with earlier twentieth century rhetorical articulations of humans as "symbol-using animals," as Kenneth Burke has asserted. Technical writing, with its dual histories as both writing for specific purposes and as nonacademic writing, asserts an identity separate from the academic study of writing and pedagogy in the first year composition class, yet shares much of the same rhetorical basis and intellectual history. Two threads characterize this identity of professional and technical communication. The first larger group is comprised for the most part of professionals working in a variety of fields, from doctors to lawyers to engineers, programmers, and managers, all of whom spend a sizeable amount of their working time writing. These are the professionals writing who need the support of the second, smaller group of professional technical writing researchers who can articulate best practices and research-based solutions to problems shared by a variety of professionals who need to write effectively. This second group of professional writers, technical communication scholars, and rhetoric researchers will also find themselves increasingly called upon to solve challenging communication problems faced by professionals from various fields of postindustrial work as new media and new economy challenges require innovative solutions.

Test Collections

Ben Carterette

Department of Computer and Information Sciences, University of Delaware, Newark, Delaware, U.S.A.

Abstract

Research and development of search engines and other information retrieval (IR) systems proceeds by a cycle of design, implementation, and experimentation, with the results of each experiment influencing design decisions in the next iteration of the cycle. Batch experiments on *test collections* help ensure that this process goes as smoothly and as quickly as possible. A test collection comprises a collection of documents, a set of information needs, and judgments of the relevance of documents to those needs.

INTRODUCTION

In the early 1960s, a librarian employed by Cranfield Aeronautics was working on search systems to help aeronautical engineers locate research papers relevant to particular engineering questions. His systems involved combinations of cataloging and labeling methods called “precision devices”—those designed to increase the proportion of matching material that was relevant—and “recall devices”—those designed to increase the proportion of relevant material that was found.^[1] Between these two broad classes of devices, many permutations and variations were possible. He needed a way to measure the utility of one precision device over another, one recall device over another, or a precision device versus a recall device. In other words, he needed to be able to *evaluate* the devices’ performance and compare them to one another.

A straightforward way to go about this is to bring in actual users of the system, have them interact with it for a while, and measure how well and how fast they are able to complete certain tasks. Today this is called a “user-based evaluation.” While user-based evaluations are invaluable for measuring certain aspects of retrieval systems, they are also slow, expensive, and inefficient: each iteration of the design cycle requires a new study with new users, who must be compensated for their time. Meanwhile, differences between systems commingle with the abilities and preferences of the users, limiting conclusions that can be drawn about the systems independent of the particular users in the study. Finally, the data the users generate is not reusable; once a design cycle starts anew, the entire process must be started from scratch. Comparing a wide variety of systems with different (and sometimes very subtle) combinations of precision and recall devices made this process far too inefficient.

Instead, the librarian—Cyril Cleverdon—hit upon an idea that would allow them to *automatically* differentiate

between the performance of different devices. He in effect reverse engineered a user study. He assembled a collection of research papers and contacted their authors, asking them to provide the research questions that had inspired the paper. He then asked the authors to rate each of the cited references on a scale of 1–5 with regard to how relevant it was to each of the research questions. This produced data by which he could simulate a user study: the author-provided research questions were a set of information needs that would be similar to those of the system’s users, and the judgments of relevance told him which articles would be better to retrieve. The same data could be used again and again, under the assumption that the ability to answer that particular set of research questions better would generalize to the wider space of research questions that users would want to ask.

This basic method (and indeed the documents, questions, and judgments themselves) was picked up by Professor Gerard Salton of Cornell for the evaluation of his highly influential automatic text indexing and retrieval system SMART.^[2] As a result, it is now the de facto approach to evaluating automatic retrieval system performance, and it is referred to as the “Cranfield paradigm.” Evaluations within this paradigm are called “system-based evaluations.” The key component to a system-based evaluation is a *test collection*: a set of documents or other objects that will be indexed and searched, a set of information needs that are representative of the needs of typical users, and judgments of the relevance of indexed objects to those information needs.

The test collection resulting from the above study—the Cranfield collection of aeronautical engineering abstracts—consisted of 1400 documents, 225 information needs, and roughly 1800 relevance judgments, on average eight per information need. Those that were not provided by the authors were filled in by students later on. Since then, test collections have grown with the size and complexity of organization and retrieval problems. Modern

test collections in information retrieval (IR) research consist of millions of full-text documents, and in development of Web search engines, tens of billions of Web pages and other information.

This entry is about the components of a test collection, how test collections are assembled, and particular test collections used in current research and development. Before getting to that, it is important to understand how a test collection reflects a particular retrieval task and a definition of relevance.

RETRIEVAL TASKS AND RELEVANCE

People use search engines for many different reasons: library catalog search, Web search, literature search; routing and filtering; known-item search, novel-item search, passage search; question answering, summarization, media search, and so on. Each of these is a different *retrieval task*, and a test collection built to study one task is not necessarily the right collection for studying another. Each task suggests a different definition of *relevance*; since the definition of relevance affects every judgment to every document in the test collection, the use of a particular test collection entails the use of a particular definition of relevance designed to handle a particular retrieval task.

The prototypical task is called ad hoc retrieval: a user enters an arbitrary query and the engine returns a ranked list of documents that “match” the query according to some model. The query is considered a one-time event, with the corpus unchanging from the time the query is entered to the time the results are returned. This contrasts with tasks such as routing or filtering, in which the corpus changes over time and new documents are constantly checked for relevance against “standing” queries, or question answering, in which the query is a natural-language question and the ranked list consists of natural-language answers that are not necessarily literally attested in any document in the corpus. Tasks such as known-item retrieval,^[3] home page finding,^[4] and topic distillation^[5] are similar to ad hoc retrieval in the basic framework, but differ in that users performing one of these tasks is looking for something more specific than information about a topic; they are looking for (respectively) a particular document, a home page, or pages that are entries into hyperlinked sites of dispersed but relevant material. Novel-item retrieval has the goal of retrieving things—often passages rather than documents—that have *not* been seen before^[6] (where “before” is generally taken to mean “higher in a ranked list”).

More than any other factor, the retrieval task dictates the definition of relevance that is used when judging documents. In IR broadly defined, relevance is considered to be a semantic or pragmatic property of documents and queries. It is not syntactic, as in database systems: a

document cannot be considered relevant only by virtue of containing the query terms, nor can it be considered nonrelevant only because it lacks some or all query terms. Because words can have multiple meanings and concepts can be represented by words that the user has not thought of, it is always possible that a document is relevant despite containing none of the query terms (or, similarly, that a document is nonrelevant despite containing all of the query terms). The relevance of a document must therefore be assessed independently of the query and the system that retrieved it, but with respect to the retrieval task and the full information need.

To see the influence of task on relevance, consider the criteria for relevance under different tasks. In tasks like ad hoc and routing, a document is typically considered relevant if it contains any information about the topic. Known-item retrieval and home page finding require only one relevant document (or a very small set). For the topic distillation task, relevant pages may contain no information about the topic at all; it is sufficient that they be a gateway to a site about the topic. Determining whether pages are “novel” depends on knowing what has been ranked above them,^[7] or possibly on what a user has seen in the past.

Even within the domain of a particular task, relevance can be difficult to define precisely.^[8–10] Befitting the concept of system-based evaluation, the most widely used notion of relevance is *system-oriented*, in which the relevance of a document to a query is dependent only on the representations of the document and query, and not on any “external” features of the user that submitted the query, the state of the corpus, other documents in a ranking, and so on.^[11] This sort of definition clearly facilitates repeatable system-based evaluations, though other definitions by which relevance is ranking-dependent or corpus-dependent certainly do not make such evaluations impossible. Definitions of relevance that are conditioned to a greater degree on the user result in experiments that are not as easily repeatable, as a user’s needs can evolve in time even as the corpus is considered static.

There is also the question of whether relevance should be measured on a binary, graded, or continuous scale, or whether it is better treated as a preferential judgment between two or more documents.^[12] Topical relevance is typically defined on a binary scale: a document is either relevant (on-topic) or it is not. On the Web, where queries are very short, often ambiguous, and users tend not to look past the top 10 documents retrieved, relevance on a 3- or 5-point graded scale has become standard (cf. Burges, Shaked, et al.^[13] and Carterette and Jones^[14] for Web-inspired work on ranking and evaluating using graded judgments). Rorvig proposed that relevance be assessed as a relative property between two documents, which could translate into a continuous measure of utility.^[12] These decisions depend to a large extent on the task as well.

TEST COLLECTION CONSTRUCTION

Putting together a test collection that is interesting for IR research is a difficult task.^[15] The documents should be heterogeneous enough that one can expect performance to generalize to other collections, but homogeneous enough that query samples will cover a fair amount of the possible space of information needs. The information needs should be representative of the space of needs users of the corpus will have, and large enough that statistically significant conclusions about systems can be reached. They should not be too easy for the systems (i.e., an untuned system should not be able to find all of the relevant documents), but they should not be too hard either (an untuned system should be able to find at least a few relevant documents). Queries that are too easy or too hard are not the ones that one can expect to achieve gains on through research and development, and thus are not ideal for testing. It should be noted that *some* easy and hard queries should be interspersed in the set. If a system cannot answer the easiest query, it is clearly a poor system; further testing is not required.

Tague-Sutcliffe explicates some of the particular considerations in the construction of a test collection.^[16] In assembling a corpus, one must consider “size, concentration, form, medium, subject coverage, and warrant or expected use of the database,” which in turn refer to the number of documents, the degree of homogeneity among them, the “completeness of the representation” (short citation, abstract, full-text), the “communication medium” (text, sound, video). All of these are to some extent influenced by the task (the expected use of the database). As for queries, it is preferable that they come from real users of the system, but, as Tague-Sutcliffe says, this is often more difficult and expensive than one might think, particularly when it comes to vetting their queries for coherence and ease. Artificial queries can be generated from the documents (for example, by using words in document titles), or the researcher/developer can “backfit” queries to fit a particular set of documents.

Then there is the issue of relevance judgments. Since these are semantic (or pragmatic) judgments, they require some human input. Typically they are made by assessors hired expressly for the purpose of making relevance judgments. Sometimes these assessors may provide information needs and queries as well; it stands to reason that the person best equipped to judge a document is the one who came up with the information need that retrieved it. The standard way to collect relevance judgments is by *system pooling*.^[17] the set of test queries is run through the set of systems to be compared, and the top *N* results from each system for each query are pooled. This entire pool is then judged for relevance. This focuses the judging effort on those documents least likely to be nonrelevant, and allows exact understanding of precision (the proportion of retrieved documents that are relevant) up to rank *N*. It

leaves some uncertainty in recall (the proportion of relevant documents that were retrieved), since there may be relevant documents that were not retrieved by any system and thus unjudged by any assessor.

In practice, a retrieval system developer may have a corpus ready to be searched, for example an intranet, a large database of short texts, or a collection of books, and a set of information needs that can be sampled. The problem is not in finding a corpus or information needs, but in acquiring enough relevance judgments that will allow them to have confidence in the evaluation.

Repeatability and Reusability

In an ideal setting, system-based evaluations over test collections are *repeatable*: the same experimental environment produces the same results every time. This means that published results can be verified by other researchers and developers, and results can be directly compared across developers and over time. Additionally, an ideal test collection is *reusable*: though its relevance judgments may have been collected from a particular set of systems, they should be complete enough that they can reliably evaluate new systems with properties that are as yet unknown. This way, new systems can be reliably compared to old; as well, the high cost of collecting judgments can be amortized over many experiments.

If a test collection contains a relevance judgment of every document to every query, it goes without saying that the test collection is reusable. Test collections constructed using the pooling method are not so complete, which raises the question of whether they are reusable. This was answered in the positive for a class of collections (the *TREC collections*; see below) by Zobel;^[18] while pooling failed to find up to 50% of the relevant documents for some of the test queries, these missing judgments did not seriously affect comparisons between systems. It is likely that pooling requires some degree of diversity among systems that has not been measured, and in a setting in which such diversity is not available, test collections may be less reusable.

Assessor Agreement

The system-oriented notion of relevance treats it as a *semantic* property, concerned with the meaning of the query and the document. User-oriented approaches are *pragmatic*, concerned more with what is needed by the user at the time the query was entered. In either case, relevance judgments are subject to disagreement among assessors.

The effect of disagreement on system-based evaluations is an important one and deserving of study. Cormack et al. proposed a method for acquiring relevance judgments called “Interactive Searching and Judging” (ISJ), by which assessors submit a query to a retrieval engine,

judge retrieved documents, and then reformulate the query based on what they have learned in making those judgments.^[19] Using this method to acquire judgments for a particular widely disseminated set of information needs produced a set of judgments that overlapped only 33% with the provided judgments. Despite this, the evaluation of systems over those topics did not substantially change; other studies have independently reached the same conclusion.^[20,21] This suggests that evaluations are rather robust to disagreement between assessors. Presumably there is much greater agreement on some documents than others, and those documents that assessors agree highly on tend to be the ones that are most useful for differentiating between systems.

AVAILABLE TEST COLLECTIONS

Some of the test collections that have appeared most frequently in the literature are the Cranfield collection of aerodynamics technical papers, the OHSUMED corpus of medical abstracts, the CACM corpus of abstracts from *Communications of the ACM*, the INSPEC corpus, the Text REtrieval Conference (TREC) news corpora, consisting of articles from the *New York Times*, *Wall Street Journal*, *Associated Press*, and more, and the TREC GOV corpora, consisting of millions of Web pages in the .gov domain. The first four of these contain fewer than 30,000 documents; it is only in the last 20 years that large test collections have become widely available for IR research.^[22] Each of these has an associated set of information needs either taken from actual needs of users of the corpus or developed for the express purpose of retrieval research.

In 1980, a corpus of 11,000 documents was considered “unusually large” (q.v. Robertson et al.^[23]). Part of the reason is the computational power available at the time, of course, but by 1990 corpus sizes had not grown significantly larger.^[22] I have not found any paper before 1992 using a collection of more than 30,000 documents. Tague-Sutcliffe and Hawking have both observed that the limited size of these test collections limits the conclusions that can be drawn about system performance; as a result, small collections like Cranfield, CACM, OHSUMED, and INSPEC are no longer in wide use.

IR research has been a fast-moving field, and as a result, in its early days small collections that had been developed for one task were often coerced into use for another. This was partially due to the cost of constructing a test collection: though cheaper than a series of user studies, there is still a significant startup cost that a small research group cannot necessarily afford. This was one of the motivating factors for the TREC, which began in 1992.^[22,24] The first large-scale test collections for general research purposes came out of TREC: Where previous collections had been no more than several megabytes of

short text articles, the new TIPSTER collection was about 3 GB and consisted of over a million full-text documents from the Associated Press, Wall Street Journal, and Federal Register, along with abstracts from the Department of Energy.^[24] The sets of information needs were smaller (50 topics rather than the several hundred queries in previous collections), but more tightly focused, well-defined, and assembled with greater quality control.^[22] This collection was developed for the standard ad hoc task, and in the intervening time more documents and queries have been added, new domains sampled, and new tasks represented. Today there are research test collections with up to 25 million documents and tens of thousands of queries (though the relevance judgments are very sparse). There are test collections designed for many different tasks, including routing and filtering, home-page finding, known-item finding, topic distillation, question answering, expert finding, patent search, and many more.

The collections produced by TREC, which are available from TREC’s Web site (<http://trec.nist.gov>) are now standard and ubiquitous in IR research. Similar evaluation conferences such as NTCIR (NII Test Collections for IR Systems; <http://research.nii.ac.jp/ntcir>) and CLEF (Cross-Language Evaluation Forum; <http://clef-campaign.org>) have emerged to provide a greater breadth of data for retrieval in other languages and for other tasks (such as patent retrieval, image retrieval, and video retrieval) as the field has grown substantially over the last decade.

CONCLUSION

A test collection comprises a set of documents, a set of information needs or queries, and a set of judgments of relevance of documents to those information needs. They enable rapid IR research and development through batch evaluations of system performance.

Text Encoding Initiative (TEI)

Edward Vanhoutte

Ron Van den Branden

Centre for Scholarly Editing and Document Studies, Royal Academy of Dutch Language and Literature, Gent, Belgium

Abstract

The result of community efforts among computing humanists, the Text Encoding Initiative or TEI is the *de facto* standard for the encoding of texts in the humanities. This entry explains the historical context of the TEI, its fundamental principles, history, and organization.

INTRODUCTION

Computers can only process texts whose characters are represented by a system that relates to the binary system computers can interpret. This is called character encoding. One such character encoding scheme based on the English alphabet is ASCII (American Standard Code for Information Interchange). Character encoding facilitates the storage of text in computers and the transmission of text through telecommunication networks. Character encoding, however, does not say anything about the semantics, interpretation, or structure of a text. Such information on a text is called meta-information. If we want to add any meta-information to a text so that it can be processed by computers, we need to encode or markup texts. We can do this by inserting natural language expressions (or codes representing them) in the text with the same character encoding the text is using, but separated from the text by specific markers. One such expression, we call a tag. All of the tags used to encode a text together constitute a markup language. The application of a markup language to a text, we call text encoding.

The Text Encoding Initiative (TEI) is a standard for the representation of textual material in digital form through the means of text encoding. This standard is the collaborative product of a community of scholars, chiefly from the humanities, social sciences, and linguistics who are organized in the TEI Consortium (TEI-C <http://www.tei-c.org>). The TEI Consortium is a nonprofit membership organization and governs a wide variety of activities such as the development, publication, and maintenance of the text encoding standard documented in the *TEI Guidelines*, the discussion and development of the standard on the TEI mailing list (TEI-L) and in Special Interest Groups (SIG), the gathering of the TEI community on yearly members meetings, and the promotion of the standard in publications, on workshops, training courses, colloquia, and conferences. These activities are generally open to nonmembers as well.

By “TEI Guidelines” one may refer both to the markup language and tag set proposed by the TEI Consortium and to its documentation online or in print. Informally “TEI Guidelines” is often abbreviated to “TEI.” In this entry “TEI Guidelines” is used as the general term for the encoding standard. The *TEI Guidelines* are widely used by libraries, museums, publishers, and individual scholars to present texts for online research, teaching, and preservation. Since the TEI is expressed in terms of the eXtensible Markup Language (XML) and since it provides procedures and mechanics to adapt to one’s own project needs, the *TEI Guidelines* define an open standard that is generally applicable to any text and purpose.

The entry first introduces the concepts of text encoding and markup languages in the humanities and then introduces the TEI encoding principles. Next, the article provides a brief historical survey of the TEI Guidelines and ends with a presentation of the Consortium’s organization.

TEXT ENCODING IN THE HUMANITIES

Since the earliest uses of computers and computational techniques in the humanities at the end of the 1940s, scholars, projects, and research groups had to look for systems that could provide *representations* of data which the computer could process. Computers, as Michael Sperberg-McQueen has reminded us are binary machines that “can contain and operate on patterns of electronic charges, but they cannot contain numbers, which are abstract mathematical objects not electronic charges, nor texts, which are complex, abstract cultural and linguistic objects” (p. 34).^[1] This is clearly seen in the mechanics of early input devices such as punched cards where a hole at a certain coordinate actually meant a 1 or 0 (true or false) for the character or numerical represented by this coordinate according to the specific character set of the computer

used. Because different computers used different character sets with a different number of characters, texts first had to be transcribed into that character set. All characters, punctuation marks, diacritics, and significant changes of type style had to be encoded with an inadequate budget of characters. This resulted in a complex of “flags” for distinguishing uppercase and lowercase letters, for coding accented characters, the start of a new chapter, paragraph, sentence, or word. These “flags” were also used for adding analytical information to the text such as word classes, morphological, syntactic, and lexical information. Ideally, each project used its own set of conventions consistently throughout. Since this set of conventions was usually designed on the basis of an analysis of the textual material to be transcribed to machine-readable text, another corpus of textual material would possibly need another set of conventions. The design of these sets of conventions was also heavily dependent on the nature and infrastructure of the project, such as the type of computers, software, and devices such as magnetic tapes of a certain kind that were available.

Although several projects were able to produce meaningful scholarly results with this internally consistent approach, the particular nature of each set of conventions or encoding scheme had lots of disadvantages. Texts prepared in such a proprietary scheme by one project could not readily be used by other projects; software developed for the analysis of such texts could hence not be used outside the project due to an incompatibility of encoding schemes and nonstandardization of hardware. However, with the increase of texts being prepared in machine-readable format, the call for an economic use of resources increased as well. Already in 1967, Michael Kay argued in favor of a “standard code in which any text received from an outside source can be assumed to be” (p. 171).^[2] This code would behave as an exchange format which allowed the users to use their own conventions at output and at input (p. 172).^[2]

MARKUP LANGUAGES IN THE HUMANITIES

Procedural and Descriptive Markup

When human beings read texts, they perceive both the information stored in the linguistic code of the text and the meta-information which is inferred from the appearance and interpretation of the text. By convention, italics are, for instance, used as a code signaling a title of a book, play, or movie; a foreign word or phrase; or emphatic use of the language. Through their cognitive abilities, readers usually have no problems selecting the most appropriate interpretation of an italic string of text. Computers, however, need to be informed about these issues in order to be able to process them. This can be done by way of a markup language that

provides rules to formally separate information (the text in a document) from meta-information (information *about* the text in a document). Whereas markup languages in use in the typesetting community were mainly of a procedural nature, that is, they indicate procedures that a particular application should follow (e.g., printing a string of text in italics), the humanities were also and mainly considered with descriptive markup that identifies the entity type of tokens (e.g., identifying that a string of text is a title of a book or a foreign word). Unlike procedural or presentational markup, descriptive markup establishes a one to one mapping between logical elements in the text and their markup. In order to achieve this, descriptive markup languages tend to formally separate information (the text in a document) from meta-information (information *about* the text in a document).

Early Attempts

Some sort of standardization of text encoding for the encoding and analysis of literary texts was reached by the COCOA encoding scheme originally developed for the COCOA program in the 1960s and 1970s,^[3] but used as an input standard by the Oxford Concordance Program (OCP) in the 1980s^[4] and by the Textual Analysis Computing Tools (TACT) in the 1990s.^[5] For the transcription and encoding of classical Greek texts, the beta-transcription/encoding system reached some level of standardized use.^[6]

The Standard Generalized Markup Language (SGML)

The call for a markup language that could guarantee reusability, interchange, system and software independence, portability, and collaboration in the humanities was answered by the publication of the Standard Generalized Markup Language (SGML) as an ISO standard in 1986 (ISO 8879:1986).^[7] Based on IBM’s *Document Composition Facility Generalized Markup Language*, SGML was developed mainly by Charles Goldfarb as a metalanguage for the description of markup schemes that satisfied at least seven requirements for an encoding standard (pp. 28–29):^[8]

1. The requirement of comprehensiveness.
2. The requirement of simplicity.
3. The requirement that documents be processable by software of moderate complexity.
4. The requirement that the standard not be dependent on any particular characteristic set or text-entry device.
5. The requirement that the standard not be geared to any particular analytic program or printing system.

6. The requirement that the standard should describe text in editable form.
7. The requirement that the standard allow the interchange of encoded texts across communication networks.

In order to achieve universal exchangeability and software and platform independence, SGML made use exclusively of the ASCII codes. As mentioned above, SGML is not a markup language itself, but a metalanguage by which one can create separate markup languages for separate purposes. This means that SGML defines the rules and procedures to specify the vocabulary and the syntax of a markup language in a formal Document Type Definition (DTD). Such a DTD is a formal description of, for instance, names for all elements, names and default values for their attributes, rules about how elements can nest and how often they can occur, and names for reusable pieces of data (entities). The DTD enables full control, parsing, and validation of SGML-encoded documents. By and large the most popular SGML DTD is the Hypertext Markup Language (HTML) developed for the exchange of graphical documents over the Internet.

A markup scheme with all these qualities was exactly what the humanities were looking for in their quest for a descriptive encoding standard for the preparation and interchange of electronic texts for scholarly research. There was a strong consensus among the computing humanists that SGML offered a better foundation for research-oriented text encoding than other such schemes.^[8,9] From the beginning, however, SGML was also criticized for at least two problematic matters: SGML's hierarchical perspective on text, i.e., the representation of text as a hierarchical tree structure, and SGML's verbose markup system.^[9] These two issues have since been central to the theoretical and educational debates on markup languages in the humanities.

The eXtensible Markup Language (XML)

The publication of the eXtensible Markup Language (XML) 1.0 as a W3C recommendation in 1998^[10] brought together the best features of SGML and HTML and soon achieved huge popularity. Among the strengths XML borrowed from SGML are the explicitness of descriptive markup, the expressive power of hierarchic models, the extensibility of markup languages, and the possibility to validate a document against a DTD. From HTML it borrowed simplicity and the possibility to work without a DTD. Technically speaking, XML is a subset of SGML and the recommendation was developed by a group of people with a long standing experience in SGML, many of whom were members of the TEI community.

For example, a simple two-paragraph document could be encoded as follows in XML:

```
<?xml version="1.0" encoding="UTF-8"?>
<document>
  <!-- paragraphs go here -->
  <paragraph number="1">Paragraph one of
    <title>an XML example</title>.</paragraph>
  <paragraph number="2">Paragraph two of this
    example.</paragraph>
</document>
```

This is an example of an XML document, representing both information and meta-information. Information (plain text) is contained in *XML elements*, delimited by *start tags* (e.g., <document>) and *end tags* (e.g., </document>). Additional information to these XML elements can be given in *attributes*, consisting of a name (e.g., number) and a value (e.g., ^[1]). *XML comments* are delimited by start markers (<!--) and end markers (-->). This particular example illustrates how XML enables semantically transparent encoding of a document (<document>), which consists of two paragraphs (<paragraph>), the first of which contains text identified as a title (<title>). By providing facilities to define own tags and attributes, XML allows encoders to devise their own markup languages for their document (types).

Among more technical ones, Steven DeRose pointed out substantial advantages of XML to the TEI community: by allowing for more flexible automatic parsing strategies and easy delivery of electronic documents with cheap ubiquitous tools such as Web browsers, XML could spread the notion of descriptive markup to a wide audience that will thus be acquainted with the concepts articulated in the TEI Guidelines (p. 19).^[11] Because of its advantages and widespread popularity, XML became the metalanguage of choice for expressing the rules for descriptive text encoding in TEI.

TEI: GROUND RULES

Guidelines

The conclusions and the work of the TEI community are formulated as guidelines, rules, and recommendations rather than standards, because it is acknowledged that each scholar must have the freedom of expressing their own theory of text by encoding the features they think important in the text. A wide array of possible solutions to encoding matters is demonstrated in the TEI Guidelines which therefore should be considered a reference manual rather than a tutorial. Mastering the complete TEI encoding scheme implies a steep learning curve, but few projects require a complete knowledge of the TEI. Therefore, a manageable subset of the full TEI encoding scheme was published as TEI Lite, currently describing 145 elements.^[12] Originally intended as an introduction and a didactic stepping stone to the full recommendations, TEI

Lite has, since its publication in 1995, become one of the most popular TEI customizations and proves to meet the needs of 90% of the TEI community, 90% of the time.

The ground rules discussed in this section apply to the most recent version of the TEI at the time of writing, i.e., TEI P5. See the section on TEI: History for more details about P5 and previous versions of the TEI Guidelines.

Text Structure

The TEI Guidelines^[13] define a set of rules to mark up the phenomena in a wide range of texts in a descriptive fashion. This means that, for example, encoders can (and should) not just indicate *that* a bit of text is printed in italics, but *why* this is the case: either because it appears to be a title in a bibliographical reference, or a technical term, a foreign word, a regular word with rhetorical emphasis, and so on. Texts that are enriched with intelligible meta-information not only can be preserved and reused more easily by humans, but also can be processed more intelligently by computers.

The TEI guarantees this potential by imposing a common structure on texts:

```
<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
      <titleStmt>
        <title><!-- Title - -></title>
      </titleStmt>
      <publicationStmt>
        <p><!-- Publication Information - -></p>
      </publicationStmt>
      <sourceDesc>
        <p><!-- Information about the source - -></p>
      </sourceDesc>
    </fileDesc>
  </teiHeader>
  <text>
    <body>
      <p n="1">Paragraph one of <title>an
        XML example</title>.</p>
      <p n="2">Paragraph two of this
        example.</p>
    </body>
  </text>
</TEI>
```

This example, as any TEI text, is recognizable as a TEI text by the outermost *<TEI>* element, which is declared in the dedicated TEI namespace (<http://www.tei-c.org/ns/1.0>). The TEI considers texts units of information that are composed of two mandatory parts:

- A header (*<teiHeader>*) containing descriptive meta-information. This should minimally document following aspects of the electronic file itself (*<fileDesc>*):
 - The title statement (*<titleStmt>*), providing information about the title, author, and others responsible for the electronic text.
 - The publication statement (*<publicationStmt>*), providing publication details about the electronic text.
 - A description of the source (*<sourceDesc>*), documenting bibliographic details about the electronic text's material source (if any).
- the actual text (*<text>*) containing meta-information about the text's structure and the actual text. This should minimally contain a text body (*<body>*). The body contains lower-level text structures like paragraphs (*<p>*), or different structures for text genres other than prose: lines for poetry, speeches for drama.

Apart from simple texts, TEI provides means to encode composite texts, either by grouping structurally related texts in a *<group>* element inside *<text>*, or treating them as a corpus of diverse texts, using *<teiCorpus>* as the outermost element.

TEI Modules

As illustrated by this example, a significant part of the rules in the TEI Guidelines apply to the expression of descriptive and structural meta-information about the text. Yet, the TEI defines concepts to represent a much wider array of textual phenomena, amounting to a total of 503 elements and 210 attributes. These are organized into 21 modules, grouping related elements and attributes:

1. The TEI Infrastructure
Definition of common datatypes and modular class structures used to define the elements and attributes in the other modules.
2. The TEI Header
Definition of the elements that make up the header section of TEI documents. Its major parts provide elements to encode detailed metadata about bibliographic aspects of electronic texts, their relationship with the source materials from which they may have been derived, nonbibliographic details, and a complete revision history.
3. Elements Available in All TEI Documents
Definition of elements and attributes that may occur in any TEI text, of whatever genre. These elements cover textual phenomena like paragraphs, highlighting and quotation, editorial changes (marking of errors, regularizations, additions), data-like structures (names, addresses, dates, numbers, abbreviations),

- cross-reference mechanisms, lists, notes, graphical elements, bibliographic references, and passages of verse or drama.
4. **Default Text Structure**
Definition of elements and attributes that describe the structure of TEI texts, like front matter and title pages, text body, and back matter. These may contain further divisions, possibly introduced by headings, salutations, opening formulae, and/or concluded by closing formulae, closing salutations, trailing material, and postscripts.
 5. **Representation of Nonstandard Characters and Glyphs**
Definition of specific provisions for representing characters for which no standardized representation (such as defined by the *Unicode Consortium* <http://www.unicode.org/>) exists.
 6. **Verse**
Definition of specific elements and attributes for dedicated analysis of verse materials, such as caesurae, metrical systems, rhyme schemes, and enjambments.
 7. **Performance Texts**
Definition of specific elements and attributes for dedicated analysis of drama materials. These include provisions for encoding specific phenomena in front matter and back matter, like details about performances, prologues, epilogues, the dramatic setting, and cast lists. Other drama-specific structures include speeches and stage directions. For multimedia performances, elements for the description of screen contents, camera angles, captions, and sound are provided.
 8. **Transcriptions of Speech**
Definition of elements and attributes for (general purpose) transcription of different kinds of spoken material. These cover phenomena like utterances, pauses, nonlexical sounds, gestures, and shifts in vocal quality. Besides this, specific header elements for describing the vocal source of the transcription are provided.
 9. **Dictionaries**
Definition of elements and attributes for representing dictionaries, with provisions for unstructured and structured dictionary entries (possibly grouped). Dictionary entries may be structured with a number of specific elements indicating homonyms, sense, word form, grammatical information, definitions, citations, usage, and etymology.
 10. **Manuscript Description**
Definition of specific header and structural elements and attributes for the encoding of manuscript sources. Header elements include provisions for detailed documentation of a manuscript's or manuscript part's identification, heading information, contents, physical description, history, and additional information. Dedicated text elements cover phenomena like catchwords, dimensions, heraldry, watermarks, and so on.
 11. **Representation of Primary Sources**
Definition of elements and attributes for detailed transcription of primary sources. Phenomena covered are facsimiles, more complex additions, deletions, substitutions and restorations, document hands, damage to the source material, and illegibility of the text.
 12. **Critical Apparatus**
Definition of elements and attributes for the representation of (different versions of texts as) scholarly editions, listing all variation between the versions in a variant apparatus.
 13. **Names, Dates, People, and Places**
Definition of elements and attributes for more detailed analysis of names of persons, organizations, and places, their referents (persons, organizations, and places), and aspects of temporal analyses.
 14. **Tables, Formulae and Graphics**
Definition of specific elements and attributes for detailed representation of graphical elements in texts, like tables, formulae, and images.
 15. **Language Corpora**
Definition of elements and attributes for the encoding of corpora of texts that have been collected according to specific criteria. Most of these elements apply to the documentation of these sampling criteria, and contextual information about the texts, participants, and their communicative setting.
 16. **Linking, Segmentation, and Alignment**
Definition of elements and attributes for representing complex systems of cross-references between identified anchor places in TEI texts. Recommendations are given for either in-line or stand-off reference mechanisms.
 17. **Simple Analytic Mechanisms**
Definition of elements and attributes that allow the association of simple analyses and interpretations with text elements. Mechanisms for the representation of both generic and particular linguistic analyses are discussed.
 18. **Feature Structures**
Definition of elements and attributes for constructing complex analytical frameworks that can be used to represent specific analyses in TEI texts.
 19. **Graphs, Networks, and Trees**
Definition of elements and attributes for the analytical representation of schematic relationships between nodes in graphs and charts.
 20. **Certainty and Responsibility**
Definition of elements for detailed attribution of certainty for the encoding in a TEI text, as well as the identification of the responsibility for these encodings.

21. Documentation Elements

Definition of elements and attributes for the documentation of the encoding scheme used in TEI texts. This module provides means to define elements, attributes, element and attribute classes, either by changing existing definitions or by creating new ones.

Each of these modules and the use of the elements they define are discussed extensively in a dedicated chapter of the TEI Guidelines.

Using TEI

In order to use TEI for the encoding of texts, users must make sure that their texts belong to the TEI namespace (<http://www.tei-c.org/ns/1.0>) and adhere to the requirements of the text model proposed by the TEI. In order to facilitate this conformance, it is possible (and strongly suggested) to associate TEI texts with formal representations of this text model. These formal *structural grammars* of a TEI compatible model of the text can be expressed in a number of ways, commonly referred to as a *TEI schema*. Technically, a TEI schema can be expressed in a variety of formal languages such as *Document Type Definition* (<http://www.w3.org/TR/REC-xml/#dt-doctype>), *W3C XML Schema* (<http://www.w3.org/XML/Schema>), or the *RELAX NG* schema language (<http://www.relaxng.org/>). It is important to notice that no such thing as “the TEI schema” exists. Rather, users are expected to select their desired TEI elements and attributes from the TEI modules, possibly with alterations or extensions where required. In this way, TEI offers a stable base with unambiguous means for the representation of basic textual phenomena, while providing standardized mechanisms for user customization for uncovered features. It is a particular feature of TEI that these abstract text models themselves can be expressed as TEI texts, using the documentation elements defined in the dedicated module *Documentation Elements*. A minimal TEI customization file looks as follows:

```
<TEI xmlns="http://www.tei-c.org/ns/1.0" xml:lang="en">
<teiHeader>
  <fileDesc>
    <titleStmt>
      <title>A TEI customization</title>
      <author>generated by Roma</author>
    </titleStmt>
    <publicationStmt>
      <p>for use by whoever wants it</p>
    </publicationStmt>
    <sourceDesc>
      <p>created on Thursday 24th July 2008
        10:20:17 AM by the form at
        http://www.tei-c.org.uk/Roma/</p>
```

```
      </sourceDesc>
    </fileDesc>
  </teiHeader>
  <text>
    <front>
      <divGen type="toc"/>
    </front>
    <body>
      <p>My TEI Customization starts with modules tei,
        core, header, and textstructure</p>
      <schemaSpec ident="TBECustom" docLang="en"
        xml:lang="en" prefix=" ">
        <moduleRef key="tei"/>
        <moduleRef key="header"/>
        <moduleRef key="core"/>
        <moduleRef key="textstructure"/>
      </schemaSpec>
    </body>
  </text>
</TEI>
```

Besides the common minimal TEI structure (<teiHeader> and <text>), a TEI customization file has one specific element which defines the TEI schema (<schemaSpec>). A TEI schema must minimally include the modules which define the minimal TEI text structure: the *TEI infrastructure* module, the *core* module with all common TEI elements, the *header* module defining all teiHeader elements, and the *textstructure* module defining the elements representing the minimal structure of TEI texts.

In the vein of *Literary Programming* (<http://www.literateprogramming.com/>), a TEI customization file not only contains the formal declaration of TEI elements inside <schemaSpec>, but may also contain prose documentation of the TEI encoding scheme it defines. Consequently, TEI customization files are commonly called *ODD files* (One Document Does it all), because they serve as a source for the derivation of

- A formal TEI schema (either as a DTD, W3C XML Schema, or RELAX NG schema).
- Human-friendly documentation of the TEI encoding scheme (in HTML, PDF, or XML).

In order to accommodate the process of creating customized TEI schemas and prose documentation, the TEI has developed a dedicated piece of software called *Roma* <http://www.tei-c.org/Roma/>. This is an ODD processor, offering an intuitive Web-based interface for the creation and basic editing of ODD files, generation of according TEI schemas and prose documentation in a number of presentation formats.

A TEI schema, stating all structural conditions and restraints for the elements and attributes in TEI texts can then be used to automatically validate actual TEI documents with an XML parser. Consider, for example, following fragments:

[A]

```
<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
      <titleStmt>
        <title>A sample TEI document</title>
      </titleStmt>
      <publicationStmt>
        <publisher>
          Taylor & Francis
        </publisher>
        <pubPlace>London</pubPlace>
        <date when="2008"/>
      </publicationStmt>
      <sourceDesc>
        <p>No source, born digital</p>
      </sourceDesc>
    </fileDesc>

    <body>
      <p>This is a sample paragraph, illustrating a
        <orgName>TEI</orgName> document.</p>
    </body>
  </text>
</TEI>
```

When validated against a TEI schema derived from the previous ODD file, file [A] will be recognized as a valid TEI document, while file [B] will not:

- The TEI prescribes that the `<teiHeader>` *must* be present in each document, and that it precede the `<text>` part.
- The minimal set of TEI modules does not include the specialized `<orgName>` element. Although it is a TEI element, using it requires selection of the appropriate TEI module in the ODD file (in this case, the module for *Names, Dates, People, and Places*).

TEI: HISTORY

After the concise overview of the most recent version of TEI (P5) in the preceding section, this section explains the historical development of the TEI Guidelines.

Poughkeepsie Principles

Shortly after the publication of the SGML specification as an ISO Standard, a diverse group of 32 humanities computing scholars gathered at Vassar College in Poughkeepsie, New York in a 2-day meeting (November 11 and 12, 1987) called for by the Association for Computers and the Humanities (ACH, <http://www.ach.org>), funded by the National Endowment for the Humanities (NEH), and convened by Nancy Ide and Michael Sperberg McQueen. The main topic of the meeting was the question how and whether an encoding standard for machine-readable texts intended for scholarly research should be developed. Among the delegates were representatives from the main European text archives and from important North American academic and commercial research centers. Contrary to the disappointing outcomes of other such meetings in San Diego in 1977 or in Pisa in 1980, this meeting did reach its goal with the formulation and the agreement on the following set of methodological principles—the so-called *Poughkeepsie Principles*—for the preparation of text encoding guidelines for literary, linguistic, and historical research (pp. 132–133),^[14] (p. E.6-4),^[15] (p. 6.):^[16]

1. The guidelines are intended to provide a standard format for data interchange in humanities research.
2. The guidelines are also intended to suggest principles for the encoding of texts in the same format.
3. The guidelines should
 - a. Define a recommended syntax for the format
 - b. Define a metalanguage for the description of text-encoding schemes
 - c. Describe the new format and representative existing schemes both in that metalanguage and in prose.
4. The guidelines should propose sets of coding conventions suited for various applications.
5. The guidelines should include a minimal set of conventions for encoding new texts in the format.
6. The guidelines are to be drafted by committees on
 - a. Text documentation
 - b. Text representation
 - c. Text interpretation and analysis
 - d. Metalanguage definition and description of existing and proposed schemes coordinated by a steering committee of representatives of the principal sponsoring organizations.
7. Compatibility with existing standards will be maintained as far as possible.
8. A number of large text archives have agreed in principle to support the guidelines in their function as an interchange format. We encourage funding agencies to support development of tools to facilitate this interchange.
9. Conversion of existing machine-readable texts to the new format involves the translation of their conventions into the syntax of the new format. No

requirements will be made for the addition of information not already coded in the texts.

For the implementation of these principles the ACH was joined by the Association for Literary and Linguistic Computing (ALLC, <http://www.allc.org>) and the Association for Computational Linguistics (ACL, <http://www.aclweb.org/>). Together they established the Text Encoding Initiative (TEI) whose mission it was to develop the *Poughkeepsie Principles* into workable text encoding guidelines. The Text Encoding Initiative very soon came to adopt SGML, published a year before as ISO standard, as its framework. Initial funding was provided by the US National Endowment for the Humanities, Directorate General XIII of the Commission of the European Communities, the Canadian Social Science and Humanities Research Council, and the Andrew W. Mellon Foundation.

TEI P1 and TEI P2

From the Poughkeepsie Principles the TEI concluded that the TEI Guidelines should

- Provide a standard format for data interchange.
- Provide guidance for encoding of texts in this format.
- Support the encoding of all kinds of features of all kinds of texts studied by researchers.
- Allow the rigorous definition and efficient processing of texts.
- Provide for user-defined extensions.
- Be application independent.
- Be simple, clear, and concrete.
- Be simple for researchers to use without specialized software.

A Steering Committee consisting of representatives of the ACH, the ACL, and the ALLC appointed Michael Sperberg-McQueen as editor-in-chief and Lou Burnard as European editor of the Guidelines.

The first public proposal for the TEI Guidelines was published in July 1990 under the title *Guidelines for the Encoding and Interchange of Machine-Readable Texts* with the TEI document number TEI P1 (for Proposal 1). This version was reprinted with minor changes and corrections, as version 1.1 in November 1990.^[17] Further development of the TEI Guidelines was done by four Working Committees (Text Documentation, Text Representation, Text Analysis and Interpretation, and Metalanguage and Syntax) and a number of specialist Working Groups among which groups on character sets, text criticism, hypertext and hypermedia, formulae, tables, figures, and graphics, language corpora, manuscripts and codicology, verse, drama and performance texts, literary prose, linguistic description, spoken text, literary studies,

historical studies, print dictionaries, machine lexica, and terminological data. The extensions and revisions resulting from this work, together with extensive public comment resulted in the drafting of a revised version, TEI P2, that was released chapter by chapter between March 1992 and the end of 1993^[18] and that included substantial amounts of new material.

TEI P3

The following step was the publication of the TEI P3 *Guidelines for Electronic Text Encoding and Interchange* in 1994^[19] that presented a further revision of all chapters published under the document number TEI P2, and the addition of further chapters. A final revised edition of these P3 Guidelines correcting several typographic and other errors, and introducing one new element was published in 1999.^[20] The publication of this 1292 page documentation of the definitive guidelines defining some 439 elements marked the conclusion of the initial development work. With this work, the Poughkeepsie Guidelines were met by providing a framework for the encoding of texts in any natural language, of any date, in any literary genre or text type, without restriction on form or content and treating both continuous materials (“running text”) and discontinuous materials such as dictionaries and linguistic corpora.

TEI P4

Recognizing the benefits for the TEI community, the P4 revision of the TEI Guidelines^[21] was published in 2002 by the newly formed TEI Consortium in order to provide equal support for XML and SGML applications using the TEI scheme. The chief objective of this revision was to implement proper XML support in the Guidelines, while ensuring that documents produced to earlier TEI specifications remained usable with the new version. The XML support was realized by the expression of the TEI Guidelines in XML and the conformation to a TEI conformant XML DTD. The TEI P4 generated a set of DTD fragments that could be combined together to form either SGML or XML DTDs and thus achieved backward compatibility with TEI P3 encoded texts. In other words, any document conforming to the TEI P3 SGML DTD was guaranteed to conform to the TEI P4 XML version of it. This “double awareness” of the TEI P4 is the reason why this version was called an “XML-compatible edition” rather than an “XML edition.” This was achieved by restricting the revisions needed to make the P4 version with its 441 elements to error correction only. During this process of revision, however, many possibilities for other, more fundamental changes had been identified, which led to the current TEI P5 version of the Guidelines.

TEI P5

In 2003 the TEI Consortium asked their membership to convene Special Interest Groups (SIGs) whose aim could be to advise revision of certain chapters of the Guidelines and suggest changes and improvements in view of the P5. With the establishment of the new TEI Council, which superintends the technical work of the TEI Consortium, it became possible to agree on an agenda to enhance and modify the Guidelines more fundamentally which resulted in a full revision of the Guidelines published as TEI P5.^[13] TEI P5 contains a full XML expression of the TEI Guidelines and introduces new elements, revises content models, and reorganizes elements in a modular class system that facilitates flexible adaptations to users' needs. Contrary to its predecessor, TEI P5 does not offer backward compatibility with previous versions of the TEI. The TEI Consortium will, however, maintain and error correct the P4 Guidelines. This means that users still have the option between P4 and P5.

TEI: ORGANIZATION

The TEI Consortium was established in 2000 as a not-for-profit membership organization to sustain and develop the Text Encoding Initiative (TEI). The Consortium is supported by a number of host institutions. It is managed by a Board of Directors, and its technical work is overseen by an elected technical Council who take responsibility over the content of the TEI Guidelines.

The TEI charter outlines the consortium's goals and fundamental principles. Its goals are

1. To establish and maintain a home for the Text Encoding Initiative (TEI) in the form of a permanent organizational structure.
2. To ensure the continued funding of TEI-C activities, for example: editorial maintenance and development of the TEI Guidelines and DTD/Schema training and outreach activities, and services to members.
3. To create and maintain a governance structure for the TEI-C with broad representation of TEI user-communities.

The Consortium honors four fundamental principles:

1. The TEI Guidelines, other documentation, and DTD/Schema should be free to users.
2. Participation in TEI-C activities should be open (even to nonmembers) at all levels.
3. The TEI-C should be internationally and interdisciplinarily representative.
4. No role with respect to the TEI-C should be without term.

Involvement in the consortium is possible in three categories: voting membership which is open to individuals, institutions, or projects; nonvoting subscription, which is open to personal individuals only; and sponsorship, which is open to individual or corporate sponsors. Only members have the right to vote on consortium issues and in elections to the Board and the Council, have access to a restricted Web site with prerelease drafts of Consortium working documents and technical reports, announcements and news, and a database of members, sponsors, and subscribers, with contact information, and benefit from discounts on training, consulting, and certification. The Consortium members meet annually at a Members' Meeting where current critical issues in text encoding are discussed, and members of the Council and members of the Board of Directors are elected. The membership fee payable varies depending on the kind of project or institution and its location depending on where the economy of the member's country falls in the four-part listing of Low, Lower-Middle, Middle-Upper, and High Income Economies, as defined by the World Bank.

CONCLUSIONS

Computers can only deal with explicit data. The function of markup is to represent textual material into digital form through the explicating act of text encoding. Descriptive markup reveals what the encoder thinks to be implicit or hidden aspects of a text, and is thus an interpretive medium which often documents scholarly research next to structural information about the text. In order for this research to be exchangeable, analyzable, reusable, and preservable, texts in the field of the humanities should be encoded according to a standard which defines a common vocabulary, grammar, and syntax, while leaving the implementation of the standard up to the encoder. A result of communal efforts among computing humanists, the Text Encoding Initiative documents such a standard in the TEI Guidelines. These guidelines are fully adaptable and customizable to one's specific project while enhancing this project's compatibility with other projects employing the TEI. For over two decades, the TEI has been used extensively in projects from different disciplines, fields, and subjects internationally. The ongoing engagements of a broad user community through the organization of the TEI Consortium consolidates the importance of the text encoding standard and informs its continuous development and maintenance.

Text REtrieval Conference (TREC)

Ellen M. Voorhees

*Information Technology Laboratory, National Institute of Standards and Technology,
Gaithersburg, Maryland, U.S.A.*

Abstract

This entry summarizes the history, results, and impact of the Text REtrieval Conference (TREC), a workshop series designed to support the information retrieval community by building the infrastructure necessary for large-scale evaluation of retrieval technology.

INTRODUCTION

The Text REtrieval Conference (TREC) is a series of annual workshops designed to support the information retrieval community by building the infrastructure necessary for large-scale evaluation of retrieval technology. The conference series is organized by the U.S. National Institute of Standards and Technology (NIST) with financial support from the U.S. defense and intelligence community. The first workshop was held in November, 1992 and there has been a workshop each year since then. Text REtrieval Conference participants are researchers in text retrieval and related natural language processing fields representing academic, commercial, and government organizations. Almost 300 organizations from six continents have participated in some TREC.

The Text REtrieval Conference is a modern example of the Cranfield tradition in which retrieval system effectiveness is evaluated through test collections. Test collections are abstractions of real user information-seeking tasks that allow researchers to quickly and inexpensively compare the relative effectiveness of competing retrieval technologies. They support tight development cycles leading to improved effectiveness in shorter development time. The Text REtrieval Conference has created a variety of publicly available test collections, has standardized the experimental methodology for using test collections, and has demonstrated the validity and efficacy of the methodology for the typical ad hoc retrieval task. In addition, TREC has extended use of the test collection methodology to new tasks. The results have been significant. Retrieval effectiveness for the ad hoc task approximately doubled in the first six years of TREC, and the retrieval techniques used for the ad hoc task have been demonstrated to be effective for other tasks as well.

This entry summarizes the history, results, and impact of TREC. The next section places TREC in the historical context that led to its inception and outlines the mechanics of how TREC works. The following section reviews what has been learned about text collection evaluation methodology

from TREC. The final main section of this entry provides an overview of the variety of different tasks that have been examined in TREC and highlights the retrieval results that have been demonstrated in those tasks.

HISTORICAL CONTEXT

Test collections were introduced in the 1960s by Cyril Cleverdon and his colleagues in the Cranfield tests, a series of experiments designed to identify appropriate indexing languages for document retrieval.^[1] A test collection consists of a set of documents; a set of information need statements, called topics in TREC; and a list of which documents in the collection should be retrieved for which need, called relevance judgments. While the use of a static set of relevance judgments to represent the user in a retrieval experiment was controversial, other researchers started using the Cranfield collection to perform different experiments. Over the course of the following 20 years, many experiments were performed and additional test collections were built. But by 1990 there was growing dissatisfaction with the methodology such that even some experimenters were questioning its usefulness.^[2] There were two main problems. First, the available test collections were small, containing at most several thousand documents and a few tens of topics. Operators of the commercial retrieval systems of the day were not convinced that techniques demonstrated on small test collections would transfer to their much larger environments. Second, there was no concerted effort on the part of different research groups to use the same data or evaluation measures. As a result, the experimental findings from different groups were usually incomparable and it was not possible to build on one another's work.

In 1991, NIST was asked to build a large test collection for use in evaluating text retrieval technology developed as part of the Defense Advanced Research Projects Agency's (DARPA) Tipster project. The National Institute of Standards and Technology agreed, and proposed that in

addition to building a large test collection, it would also organize a workshop to investigate the larger issues surrounding test collection use.

The first two TRECs had two tasks, the ad hoc task and the routing task. The ad hoc task is the prototypical retrieval task such as a researcher doing a literature search in a library. In this environment, the system knows the set of documents to be searched (the library's holdings), but cannot anticipate the particular topic that will be investigated. In contrast, the routing task assumes the topics are static but need to be matched to a stream of new documents. The routing task is similar to the task performed by a news clipping service or a library profiling system.

The National Institute of Standards and Technology supplied a common set of test documents and a set of 50 topic statements for each task. The format of the topic statements varied over the years, but generally consisted of at least a brief natural language statement of the information desired (e.g., *Document will discuss how MCI has been doing since the Bell System breakup.*). Participants used their systems to run the topics against the document collection, and returned to NIST a list of the top-ranked documents for each topic.

Since the document sets used in the first TRECs contained between 800,000 and 1,000,000 documents, they were too large for each document to be judged for each topic. Instead, TREC implemented a technique called pooling that had been suggested by Karen Spärck Jones and Keith van Rijsbergen as a way to build relevance judgments for large collections.^[3] As used in TREC, a pool for a topic consists of the union of the top X (usually 100) documents across runs submitted to that task. The documents in a pool are then viewed by a human and judged as to whether they are relevant to the topic. Documents that do not get added to the pool (because no system retrieved them at high enough ranks) are not judged but are assumed to be not relevant.

Once all the relevance judgments for all of the topics in the test set were complete, NIST evaluated the retrieval runs on the basis of the relevance judgments and returned the evaluation results to the participants. A little more than a month later, researchers who had submitted runs gathered for a workshop to discuss the results and share their experiences.

Starting in TREC-3 (1994), additional tasks, called tracks, were added to TREC, and today TREC is comprised of a constantly evolving set of tracks. The tracks serve several purposes. First, tracks act as incubators for new research areas: the first running of a track often defines what the problem *really* is, and a track creates the necessary infrastructure (test collections, evaluation methodology, etc.) to support research on its task. The tracks also demonstrate the robustness of core retrieval technology in that the same techniques are frequently appropriate for a variety of tasks. Finally, the tracks make TREC

attractive to a broader community by providing tasks that match the research interests of more groups.

In addition to the variety of TREC tracks, TREC has inspired other evaluation projects that are based on the TREC model. These projects include the Japanese National Institute of Information Test Collection for IR Systems project (NTCIR, <http://research.nii.ac.jp/ntcir/>), the Cross Language Evaluation Forum (CLEF, <http://www.clef-campaign.org/>), and the Initiative for the Evaluation of XML Retrieval (INEX, <http://inex.is.informatik.uni-duisburg.de>).

TEST COLLECTION EVALUATION METHODOLOGY

One of the motivating goals for TREC was to establish a common evaluation methodology for retrieval from realistically sized collections. The goal of having experimenters report the same evaluation measures was largely met by introducing *trec_eval*, an evaluation program that provides a common implementation for over 100 different evaluation measures. A much smaller set of measures, including the recall-precision graph, mean average precision, and precision at ten documents retrieved, has become the de facto standard by which retrieval effectiveness is characterized. But TREC has done more than provide a standard scoring routine and common data sets. The Text REtrieval Conference's scale—both the size of the test collections and the number of retrieval results—has provided a unique opportunity for validating the use of test collections and exploring the limits of the evaluation methodology. This section summarizes the findings of three such investigations: examining the effect of changes in relevance judgments, examining the effect of judging only a subset of the document collection, and examining the soundness of the conclusions reached in test collection experiments.

Consistency

One objection to test collections that dates back to the Cranfield tests is the use of relevance judgments as the basis for evaluation. Relevance is known to be very idiosyncratic,^[4] and critics question how an evaluation methodology can be based on such an unstable foundation. An experiment using the TREC-4 and TREC-6 retrieval results investigated the effect of changing relevance assessors on system comparisons.^[5] The experiment demonstrated that the absolute scores for evaluation measures did change when different relevance assessors were used, but the relative scores between runs did not change. That is, if system A evaluated as better than system B using one set of judgments, then system A almost always evaluated as better than system B using a second set of judgments (the exception was in the case where the two runs

evaluated as so similar to one another that they should be deemed equivalent). The stable comparisons result held for different evaluation measures and for different kinds of assessors, and was independent of whether a judgment was based on a single assessor's opinion or was the consensus opinion of a majority of assessors.

Completeness

An important criterion for test collections is that they be reusable, that is, they can be used to compare not only the original result sets that contributed to the pools but also subsequent result sets produced using the same topic and document sets. The use of pooling where only some documents are judged for a topic caused people to question whether TREC collections were reusable since they believed runs that had not contributed to the pools would be unfairly penalized. Examination of larger pools did confirm one aspect of the critics' fears: there are unjudged documents remaining in the collections that would have been judged relevant had they made it into the pools.^[6] Further, the quality of the final test collection does depend on the diversity of the runs that contribute to the pools and the number of documents selected from each run.^[7] But tests also showed that the TREC collections are not biased against unjudged runs. In these tests, the documents uniquely retrieved by a TREC run are treated as not relevant when that run is evaluated. The difference in the evaluation results for runs evaluated both with and without their own uniquely retrieved relevant documents has until recently been smaller than the difference produced by changing relevance assessors.^[8]

Repeating the uniquely retrieved relevant test on the very latest collections built from millions of Web pages suggests that pooling has a size dependency that prevents it from producing reusable test collections for arbitrarily large document sets.^[9] Devising new techniques for building massive test collections is thus an area of active research.

Soundness

Retrieval effectiveness is reported as an average over a set of topics because retrieval system performance is known to vary widely depending on the topic. An analysis of variance model fitted to the TREC-3 results demonstrated that the topic and system effects, as well as the interaction between topic and system, were all highly significant, with the topic effect the largest.^[10] This variability in topic performance has a profound effect on retrieval system evaluation because it is difficult to isolate the relatively small differences in performance that can be attributed to retrieval system differences.

The repository of runs that have been submitted to TREC made it possible to empirically determine the relationship between the number of topics in a test collection,

the observed difference in evaluation scores (*delta*), and the likelihood that a single comparison of two retrieval runs will lead to the correct conclusion.^[11] Once the relationship was established, it was used to derive the minimum difference in scores required for a certain level of confidence in the results given the number of topics used in the comparison. As expected, the likelihood of an erroneous comparison decreases as the number of topics used increases. The likelihood of an error also decreases as the size of *delta* increases, though requiring large differences in scores before deciding two runs are different decreases the power of the experiment. However, the percentage difference in retrieval scores required for confidence in the conclusion for 50 topics (the number of topics in a typical TREC test collection) was larger than has generally been used to signify meaningful differences in the IR literature.

This conclusion that a comparatively large difference in scores is required to have confidence that a single comparison correctly indicates the better system does not invalidate the usefulness of test collections. The primary use of test collections is not cross-system comparison but optimizing the effectiveness of a single system. Experiments with variants of a single system require much smaller absolute differences in scores to yield meaningful results because most of the variance due to system–topic interaction is controlled. In addition, the confidence in a cross-system comparison can be significantly increased by repeating the comparison using multiple collections. Even a very small difference that is consistently present in multiple collections is likely to represent a true difference among systems.

THE TRACKS

The TREC track structure enables TREC to extend the test collection paradigm to tasks other than ad hoc retrieval. The set of tracks run in any particular TREC depends on the interests of the participants and sponsors, as well as on the suitability of the problem to the TREC environment. The decision of which tracks to include is made by the TREC program committee, a group of academic, industrial, and government researchers who have the responsibility for oversight of TREC. Tracks are discontinued when the goals of the track are met, or when there are diminishing returns on what can be learned about the area in TREC. Some tracks run for many years but change focus in different years.

Fig. 1 shows many of the tracks that were run in the different years of TREC, grouping the tracks by the aspect that differentiates them from one another. The aspects, listed on the left of the figure show the breadth of the problems that TREC has addressed, while the individual tracks listed on the right show the progression of tasks within the given problem area. This section provides a

Fig. 1 A subset of the TREC tracks and the years in which they were held. The track name is given on the right while the distinguishing focus of the track is given on the left.

recap of the main lessons learned about the various tasks and aspects.

Static Text

The main task in TREC for the first eight years was the ad hoc task, a task in which systems rank the documents in a known document set against not previously seen topics. The eight years of the task produced eight test collections, each consisting of a document set, a set of 50 topics, and a set of pooled relevance judgments. The document sets consist of full-text documents, mostly news articles with some government documents and a small amount of other types of documents also included. The final three years of the task (TRECs 6–8) used the same document set, so the combination of the topics and relevance judgments from those years represents a test collection with 150 topics.

Improvement in retrieval effectiveness cannot be determined simply by looking at TREC scores from year to year. It is invalid to compare the results from one year of TREC to the results of another year since any differences are likely to be caused by the different test collections in use. However, developers of the SMART retrieval system kept a frozen copy of the system they used to participate in each of the eight TREC ad hoc tasks.^[12] After every TREC, they ran each system on each test collection. For every test collection, the later versions of the SMART system were much more effective than the earlier versions of the SMART system, with the later scores approximately twice that of the earlier scores. While this is evidence for only one system, the SMART system results consistently tracked with the other systems' results in each TREC, and thus the SMART results can be considered representative of the state of the art at that time. The improvement was evident for all evaluation scores that were examined, including mean average precision and precision and recall at various cutoff levels.

The results from the top-performing systems in the ad hoc task suggest the increased effectiveness arose from improvements in two general areas, query expansion, and indexing of full-text documents. The most common way of expanding the query is to use pseudorelevance (or blind) feedback: retrieve a first set of documents using the original query; assume the first X documents are relevant; perform relevance feedback with that set of documents to create a new query (usually including both new terms and refined query weights); and return the results of searching with the new query to the user. Doing a similar type of expansion but using a document set other than the target collection has also been effective. For document indexing, the following best practices emerged from the ad hoc task results:

- Tokenization that regularizes word forms is generally helpful. The most common form of regularization is stemming, but normalizing proper nouns to a standard format can also be helpful.
- Simple “phrasing” techniques are generally helpful. The most helpful part of phrasing is the identification of common collocations that are then treated as a single unit. More elaborate schemes have shown little benefit.
- Appropriate weighting of terms is critical. The best weighting schemes reflect the discrimination power of a term in the corpus and control for document length. There are several different weighting schemes that achieve these goals and are equivalently effective. Language modeling techniques are both effective and provide a theoretical justification for the weights assigned.

Streaming Text

The second task in the first TRECs was the routing task. In the routing task, systems used old topics with known relevance judgments to produce queries that were then used to rank a new document set. A more realistic formulation of this task emerged several years later as the filtering track. In a filtering task a system makes a binary decision for each document in a document stream whether to retrieve that document in response to a standing query. There are different variants of the task depending on the timing and amount of feedback (relevance information) the system is given. Effectiveness in the filtering track was generally evaluated using a utility measure in which the system gained one amount of points for correctly retrieving a relevant document and lost a lesser amount of points for incorrectly retrieving a nonrelevant document. Comparison between routing and filtering results from the same systems demonstrated that forcing a binary retrieval decision is a much more difficult problem than simply ranking documents since the former requires setting a retrieval threshold.

Human in the Loop

The interactive track was one of the first tracks to be added to TREC. The goal of the interactive track was to study text retrieval systems in interaction with users, where both the process and the final search outcome are of interest. A main difficulty of studying the interactive behavior of retrieval systems is that searchers and topics generally have a much larger effect on search results than does the retrieval system used.

The experimental design of the TREC-6 interactive track included the use of a common baseline system.^[13] The particular retrieval system used at a site (an experimental system) was compared to the common control system that was also run at each site. The direct comparison between the experimental and control systems was used to derive a measure of how much better the experimental system was than the control, independent of topic, searcher, and any other site-specific effects. The expectation was that different experimental systems could then be indirectly compared across sites relative to the common control. Unfortunately, analysis of the track results could neither confirm nor refute the equivalence of the direct and indirect comparison of systems, and without clear positive evidence for the usefulness of the control system it was difficult to justify the cost of adding another system to an experimental design.

Beyond English

Another of the early tracks to be introduced into TREC was the Spanish track. The task in the Spanish track was a basic ad hoc retrieval task except the topics and documents were written in Spanish rather than English. The track was discontinued when the results demonstrated that retrieval systems could retrieve Spanish documents as effectively as English documents. Another single language track, this time using Chinese as a language with a very different structure than that of English, was introduced next. Again, systems were able to effectively retrieve Chinese documents using Chinese topics.

A successor to the single language tracks was the cross-language track. A cross-language retrieval system uses topics written in one language to retrieve documents written in one of a variety of languages. In the first TREC cross-language track participants searched for documents in one target language using topics written in a different language. Later versions of the track had participants search for documents using topics in one language against the entire combined document collection; still later versions of the track used more disparate languages (English topics against either Chinese or Arabic document sets). One of the unexpected results of the cross-language track was the demonstration that cross-language retrieval can be more effective than the corresponding monolingual search due to the expansion that results from translating the query.

Beyond Text

In addition to testing the ability of retrieval systems to retrieve text written in languages other than English, TREC contained a series of three tracks designed to test the ability of systems to retrieve information encoded in media other than electronic text. In the confusion track, systems retrieved documents that were the output of an OCR process. In the spoken document retrieval track, systems retrieved documents that were the output of speech recognition systems. In both tracks, the goal was to measure the effect of mistakes in the text (i.e., corrupted text) on retrieval effectiveness. The results in both tracks suggested that natural language is sufficiently redundant that error-filled text can be retrieved as effectively as clean texts for error rates likely to be seen in real-life applications. For speech recognition output, the worst effect on retrieval effectiveness was out of vocabulary (OOV) words. Participants compensated for OOV words by using adaptive language models to limit the number of OOV words encountered, and by expanding recognized text by related clean texts to include OOV words in the documents.

The video track focused on retrieving information recorded in digital videos. A document in the track was defined as a video shot, and ad hoc search topics were expressed as textual statements of information need, possibly including a still or video image as an example of the type of information sought. Unlike OCR and speech recognition output, there is no obvious way of reducing video to a set of words. As a result, there is little overlap in the techniques used to retrieve text documents versus video documents. The video track was spun off from TREC as its own TRECVideo evaluation workshop in 2003 (see <http://trecvid.nist.gov>) and continues to date.

The Web and Size

While two gigabytes of text was a large amount of text when TREC began, it was soon eclipsed by the ever-growing stores of information commercial retrieval engines were searching, especially with the advent of the World Wide Web. A series of tracks explored the related issues of Web search and retrieval efficiency in the context of document collections much larger than the TREC ad hoc collections.

The first of these tracks was the very large corpus (VLC) track. The track used a 100 gigabyte static subset of the Web as its test set and evaluated systems on both precision of the top 20 documents retrieved and speed at which the results could be assembled. This naturally led to a Web track to investigate information-seeking tasks on the Web. Web search is different from searching other large data sets in several important ways, including the massive link structure, the lack of editorial control, the different uses of search on the Web (finding information, locating services, navigating the link structure), and the use of active content. The main results of the Web track

were to demonstrate that the different search tasks require different strategies for best effectiveness. Traditional retrieval methods based on page content generally worked well for information-seeking topics, for example, whereas navigational queries such as finding a home page required making use of the link structure (such as using anchor text or link counts). The terabyte track (which actually used a 426 gigabyte crawl of the .gov domain) returned to the search efficiency focus while also exploring the question of how best to build reusable test collections for massive data sets. Getting an unbiased judgment set through traditional pooling for document sets of this scale is too expensive because too many documents must be judged. Alternative sampling strategies have been suggested but remain to be adequately vetted.

Question Answering

While a list of on-topic documents is undoubtedly useful, even that can be more information than a user wants to examine. The TREC question answering track was introduced in 1999 to focus attention on the problem of returning exactly the answer in response to a question. The initial question answering tracks focused on factoid questions such as “Where is the Taj Mahal?”. Later tracks have incorporated more difficult question types such as list questions (a question whose answer is a distinct set of instances of the type requested such as “What actors have played Tevye in “Fiddler on the Roof?”) and definition/biographical questions (such as “What is a golden parachute?” or “Who is Vlad the Impaler?”).

The question answering track was the first large-scale evaluation of open-domain question answering systems, and it has brought the benefits of test collection evaluation observed in other parts of TREC to bear on the question answering task. The track established a common task for the retrieval and natural language processing research communities, creating a renaissance in question answering research. This wave of research has created significant progress in automatic natural language understanding as researchers have successfully incorporated sophisticated language processing into their question answering systems.

Domain-Specific Retrieval

Domain-specific retrieval tasks look to exploit knowledge about the subject area to improve retrieval effectiveness. Implementing domain-specific evaluation tasks requires people with expertise in the domain to create topics and perform relevance judgments.

The first domain-specific track in TREC was the genomics track. The scenario assumed in the track was that of a biological researcher (that is, someone who already has considerable domain knowledge) confronted with the need to learn about a new gene very quickly. The track included a number of different types of tasks in the different years it

was run including ad hoc document retrieval, passage retrieval, document classification, and aspect retrieval. Topic development and relevance judgments were made by people with a background in biology; in several years the topics were derived from information needs solicited from practicing biologists. Results of the track showed that careful use of domain resources could improve retrieval effectiveness, though good generic retrieval technology was surprisingly competitive.

The legal track is focused on a specific aspect of retrieval in the legal domain, that of meeting the needs of lawyers to engage in effective discovery of digital documents. Currently, it is common for the two sides involved in litigation to negotiate a Boolean expression that defines the set of documents that are then examined by humans to determine which are responsive to a discovery request. The goal of the track is to evaluate the effectiveness of this and other search technologies in facilitating the discovery process. The track uses hypothetical complaints and corresponding requests to produce documents developed by practicing lawyers as topics. Relevance judgments are made by legal professionals who follow their typical work practices in reviewing the documents. The track is relatively new having started in 2006. Results to date have demonstrated that several different techniques including the Boolean query produce document sets that have similar numbers of responsive documents yet retrieve only some responsive documents in common. This is an important finding since high recall (the need to find most of the responsive documents) is a requirement of the real-world task.

Personal Documents

The final two tracks are distinguished by the personal nature of the documents used in the track. In the spam track the document set is an e-mail stream; in the blog track the document set is a large collection of blog pages.

The goal in the spam track was to evaluate how well systems are able to separate spam and ham (non-spam) when given an e-mail sequence. The primary difficulty in performing such an evaluation is getting appropriate corpora to use in a public test. Making real e-mail streams public is not possible due to privacy concerns, but artificially generated streams and privacy-protecting modifications to real streams tend to compromise the information used by classifiers to distinguish spam and ham. The track solved this problem by requiring filters to conform to the interface defined by a software jig and having participants submit filters to be run on the sequestered private e-mail stream. The overall results of the spam track were consistent across the three years in which it was run. Detecting spam is easier when feedback is frequent and plentiful, but even in the more difficult cases filters were able to detect the vast majority of spam with high accuracy. There was no indication that more recent spam was any harder to detect than earlier spam, though the total amount of spam included in the private stream (which included all of the

mail sent to a single individual in three distinct time periods corresponding to the different years of the track) increased significantly over the years while the amount of ham stayed roughly constant.

Blog pages are personal in that they are often used to express an opinion of the author. They are also interesting as retrieval test documents because language use within blog pages tends to be more informal than in other types of documents. The main task within the blog track has been to find documents that contain an opinion about the target cited in the topic statement. Results of the track to date show that the effectiveness of finding opinion documents is strongly dominated by a system's ability to find topically relevant documents.

CONCLUSION

When TREC began, there was real doubt as to whether the statistical systems that had been developed in the research labs (as opposed to the operational systems that used Boolean searches on manually indexed collections) could effectively retrieve documents from "large" collections. Text REtrieval Conference has shown not only that the retrieval engines of the early 1990s did scale to large collections, but that those engines have improved since then. This effectiveness has been demonstrated both in the laboratory on TREC test collections, and by today's operational systems that incorporate the techniques. Further, the techniques are routinely used on collections far larger than what was considered large in 1992. Web search engines are a prime example of the power of the statistical techniques: the ability of search engines to point users to the information they seek has been fundamental to the success of the Web.

At the time of this writing TREC 2007, the 16th TREC workshop, has just concluded. Plans are underway for TREC 2008, and it is expected that TREC will continue for the foreseeable future. The TREC Web site, <http://trec.nist.gov>, contains a wealth of information about TREC including the full proceedings for each of the workshop (in the Publications section) and details regarding how to obtain the test collections (in the Data section). The call for participation in TREC is issued each December and is posted on the main page of the TREC Web site while it is active.

Theft, Vandalism, and Security in Libraries and Archives

Sydney C. Van Nort

The City College of New York, The City University of New York, New York, U.S.A.

Abstract

The scope of library theft is difficult to determine because accurate statistical data regarding annual losses of library materials in the United States are not available. Possibly over \$25 million worth of library materials continue to come up missing from American library shelves, and the unauthorized accessing, and possible tampering, with digital collections or administrative records can be a problem as well. Book dealers can be effective allies in combating library theft, whether the perpetrator is a patron or a staff member. The notorious cases of theft by Daniel Spiegelman from the Columbia University Rare Book and Manuscript Library collections and of Stephen Carrie Blumberg, whose collecting mania spurred him to help himself to items from 327 libraries, are summarized. These cases illustrate the difficulties of detection or deterrence without the effective application of legal statutes and sentencing. The importance of the implementation of consistent security measures, whether it is the installation of security systems or policies as a planning process for the prevention of this type of disaster, is stated. Some suggested measures for theft prevention mentioned here are the installation of alarm systems, video surveillance, patron searching upon exiting, materials marking, and the use of colored photocopy paper. The need for effective communication among librarians and book dealers for the reporting and possible prevention of theft losses is noted.

SCOPE OF THE PROBLEM

When I first approached this topic in 1992, I discovered that there was very little accurate data that had been compiled indicating losses due to thefts or attrition of library materials. The best figures that were available were estimates, which was astonishing for a profession that prides itself on collecting such accurate data regarding circulation figures and the number of volumes and journals that are collected. (These are used as one measure of comparison among libraries for ranking their collections.) Katherine Keyes Leab was the administrator of formerly the only computerized database of reports of missing library items operating in the United States, Bookline Alert: Missing Books and Manuscripts (BAMBAM). As she expressed it, “one of the problems is that there are no numbers. That in itself is significant.”^[1] Unfortunately, she has discontinued it for lack of financial support.^[2] Others in the profession agree. Ronald Lieberman, former chair of the Security Committee of the Antiquarian Booksellers’ Association of America (ABAA), concurred that there is “no good substantial statistical information available at this time.”^[3]

The International League of Antiquarian Booksellers has established a database for compiling reports of stolen books since June 15, 2010, and the Antiquarian Booksellers Association encourages the reporting of thefts on The New Antiquarian—a blog on the security section. These two sources can provide current data regarding the problem. The Antiquarian Booksellers blog includes

postings regarding security issues, with a minority actually reporting a specific theft. There were nineteen thefts reported from libraries in 2013 to the International League of Antiquarian Booksellers database, and sixteen thefts were reported from libraries in 2014 (only one of those was from an American library), and the majority of the reports posted during both years were primarily from book dealers and book collectors.^[4]

The Rare Book and Manuscript Section of the Association of College and Research Libraries (ACRL), affiliated with the American Library Association (ALA), has a blog for the posting of thefts. For the year 2013, there are ten thefts reported, four from U.S. libraries, one from Canadian institutions, and five from foreign libraries. During 2014 six American libraries and institutions reported thefts.^[5]

One estimate from Alice Harrison Bahr in 1978 stated that

In the United States, where the nation’s libraries contain an estimated 1.5 billion volumes, a loss of even 1% annually amounts to some 15 million books. Again, using an average cost of \$15 to replace a missing book, the total amount replacement cost would be \$225 million. This is more than 10% of what libraries spend annually. The 15 million volumes are almost 16% of the 95 million volumes added annually by the nation’s libraries.^[6]

And many of the items stolen from libraries are worth far more than \$15. Rare books and manuscripts present an especially inviting target. A well-known book theft

scholar, Lawrence S. Thompson, noted the increasing activity of professional thieves which has made "the record of major thefts in the last 15 years ... little short of appalling." Current reports back him up.

Whether spurred on by love or greed, book theft has become a serious, costly problem and one that is not easily solved. Studies indicate that electronic security systems can be effective book theft deterrents, but alternative theft prevention programs have also been successful. Evaluation of theft control programs is in a state of flux. The only program librarians unanimously find unworkable is the honor system. In 1968 the Tarlton Law Library in Texas left legal treatises on open shelves to test the honor system. At the end of one year over \$4000 worth of material had been lost.^[7]

Another factor that contributed to the problem being underreported and neglected is that in the past it was more common for an institution not to report the theft than to report it. This was usually due to concerns about offending or driving away potential donors. Sometimes elaborate measures have been taken to recover the stolen items, even going so far as to buy them back at auction rather than explaining to the dealer before the sale and presenting proof of ownership to be awarded custody of the items through replevin.

Communication among librarians and with book and manuscript dealers is the best defense against this sort of criminal activity. For the most part, book dealers are honest; they will post notices in their trade newsletters regarding any unscrupulous dealer activity and warn their colleagues not to deal with him or her for the next five years. This type of crime needs to be taken more seriously. Art theft, which includes book theft, is the second most prevalent type of crime after narcotics activity internationally. It affects a similar percentage of victims, including institutions.^[8]

Data regarding cases of art theft have been compiled for the United States by the Federal Bureau of Investigation (FBI) and by the International Foundation for Art Research (IFAR) in New York. Even so, firm statistics regarding the recovery rate of these stolen items do not exist either; only estimates can be made. According to Constance Lowenthal of the IFAR, the recovery rate of stolen art items is about 10%. (Less than 14% of art stolen internationally is ever recovered and returned to its rightful owner.) This is not a firm statistic because the owners of the items do not always report the recovery of their items to the authorities that were notified at the time of the theft. For famous works of art, the recovery rate is closer to 50%, but this is also an estimated figure, and these figures are not linked to whether the thefts were initially made public or not.^[9] The motive for such crime is clearly monetary gain since the average art theft broken down statistically nets the thief approximately \$25,000 per item or \$50,000 per incident. This is in contrast to the

average bank robbery that only nets the thief approximately \$1400 in cash per incident.^[10]

The FBI has been primarily involved in the investigation of theft and recovery of other types of property in the United States, that is, other than books and library materials, although they have investigated thefts of large numbers of library materials stolen, often reported as missing from more than one institution. One major focus of their investigation has been into art thefts, and as an aid in this matter, they created the National Stolen Art File (NASF) in May of 1979. This database includes information on approximately 5000 paintings, prints, and sculptures valued at \$2000 or more that have been reported as stolen. The database is updated annually, and when a stolen art object is reported as having been recovered, the report is removed from NASF. Although this database primarily records data concerning stolen art items, valuable manuscript items are also included.^[11]

The problem of library and archival theft has not been at the forefront of institutional concerns, but estimated losses such as these suggested by Alice Harrison Bahr indicate that perhaps they should be. Many institutions have been more occupied with budgetary planning and the constraints placed on them by lack of sufficient funds and the subsequent impact on the level of staffing or on collection maintenance, development, or expansion. Libraries have to assess the rate of depletion of materials in their collections because in order to maintain services for their users, materials that are not returned or recovered will have to be replaced. The problem of theft of materials, either in their entirety or partially by the mutilation of certain pages from a volume, should receive greater attention because when materials are missing from a collection, it not only detracts from the integrity of that collection, but it detracts from the collective cultural heritage.^[12] This was acknowledged in the sentencing of Daniel Spiegelman by Judge Lewis Kaplan for the theft of forty items from Columbia University.^[13] Replacement of stolen or mutilated library books is sometimes an option because duplicates can be purchased, either in reprint or in a microfilm of the volume that may be available, but archival materials are unique, and when they are gone it is very difficult to obtain another item of comparable value to the collection, either from the same record-creator or concerning the same subject matter from the same time period.

The topic of library theft has not gone unnoticed in the library profession. The published literature in the librarianship and archival journals discuss incidents of theft of materials from institutions that are open to the public where presumably some of their visitors have helped themselves to the books and manuscripts from those collections and kept them.^[14] Sometimes they attempt to sell the materials to book and manuscript dealers or sometimes to a librarian, which can lead to their arrest.^[15]

Alerting these or any other organizations that might be appropriate that materials are missing from the collection is only the first step. An accurate inventory of which items have been determined to be missing should be drawn up listing the appraised value of the items and describing them in as much detail as possible, mentioning if they are marked items (and if so, where the markings appear) and if they have any other distinguishing markings or evidence of any repair work. The investigation of the theft can take a long period of time, so a chronology of all events related to the investigation should be compiled from the day the theft is reported until the materials are recovered and/or a suspect in the theft is prosecuted and, hopefully, convicted.^[16]

Two of these organizations (BAMBAM and the FBI) established a national database for logging the reports of stolen or missing items, and the third (ABAA) has a network for dissemination of this information. ABAA, due to its close links with the book dealer trade in America, has traditionally been in a good position to get the word out to book dealers that certain items have been reported as stolen through a regular column in *Antiquarian Bookman* that circulates widely in the trade. Daniel Leab and Katharine Keyes Leab, as the editors of *American Book Prices Current*, founded BAMBAM in 1981 as a nonprofit database whereby libraries could log onto their system directly and record the information regarding lost and stolen items. This system did not usually operate in this manner, since more frequently the reporting officer for the library telephoned Katharine Leab and report the information to her to be entered into the system.^[17] However, the entry of data into this system was not organized into a standardized format, such as the machine-readable or MARC format used by other data systems, which made it difficult to search efficiently because the data was sometimes entered by library staff members and sometimes by staff members at BAMBAM. When an item was reported as having been recovered, the record was deleted from BAMBAM's database. The lack of standardization meant that the compilation of accurate statistical information about the thefts reported on the database could not be compiled. A plan to incorporate the reporting features of BAMBAM with the MARC format was formulated. Katharine Leab coordinated BAMBAM for fourteen years, and negotiations fell through to get the Online Computer Library Center (OCLC) to administer it instead and standardize the data into MARC format in conjunction with ABAA and the Rare Book and Manuscript Security Committee Section of ALA,^[18] and as mentioned earlier, it has been terminated.

As of May 1992, there were 1400 records in the BAMBAM database, but not all of those records were for individual items; some of them represented entire archives.^[19] In July of 1984, 118 items were listed in BAMBAM^[20] and in the summer of 1987, 77 items were listed.^[21] With sporadic figures such as these, it is

impossible to determine overall annual trends. Hopefully, according to Ronald Lieberman, the OCLC database would have been a useful tool for providing this type of information and to help determine the patterns of losses.^[22] Susan Allen, of the Special Collections Department at the Claremont Colleges and former chair of the Rare Book and Manuscript Section of the ALA, is presently also attempting to gather statistical data on library thefts. During the week of April 20–24, 1992, she sent an electronic mail message to various colleagues at other libraries in the United States to ask if anyone had compiled figures of such reports and to ask for their help in such an effort. Since 1987 she has compiled the reports of items reported missing throughout the country that she has become aware of and has kept a narrative list.^[23]

These databases have also been created in response to a rising crime rate in the United States as a whole, which has included crimes in libraries, archives, and art museums. Evidence of this problem has been compiled by Alan Jay Lincoln, who served as the editor of a special issue of *Library Trends*, "Protecting the Library."^[24] Trends in library crimes, which include thefts of library, patron, and staff property as well as assaults of patrons and staff members are reported in *Crime in the Library: A Study of Patterns, Impact and Security*^[25] and in *Library Crime and Security*, which was coauthored by Carol Zall Lincoln and appeared in *Library and Archival Security*.^[26] Alan Jay Lincoln does not only report the problem of library crime, he also includes suggestions for combating the problem, including the installation of security systems and the implementation of new procedures.

In his introduction to the special issue on *Protecting the Library*, Lincoln states that the range of problems of crime and disruption affecting libraries has become greater, and the impact of crime in and against libraries more widespread.^[27] He continues by stating

Perhaps the oldest problem, . . . is the theft of books. The problem continues today and in many libraries is considered a major operating cost. This involves the theft of rare books by profit-oriented thieves as well as the theft of expensive but commonplace volumes by "ordinary" patrons, students, and faculty. Unlike the professional thief, others steal for selfish motives; they "need" the book, they "like" the book, they "can't find the book anyplace else," and so on. In academic libraries, the perceived competition for scarce resources entices students and faculty to take what they "must have." Of course, taking a popular volume not only improves one's own chances of success, but simultaneously reduces others' chances.

As libraries continue to develop their nonbook resources, these materials become increasingly popular targets of thieves. Episodes of theft are not confined to books. Records, tapes, software and hardware have become favored targets in some libraries. At times, these items -

as well as books - are not stolen but are mutilated, reducing both the value and usefulness of the materials. Mutilation may be in the form of slashing needed pages from journals or books. In terms of motivation, this action may be more similar to vandalism in that the perpetrator's goal is to obtain some desired material rather than destroy it. We were told of one episode of valuable information stored on computer discs being thrown in toilets by intruders. Acts of property destruction also occur with alarming regularity. Buildings are defaced and occasionally burned, equipment is damaged, and files are destroyed. Libraries also are likely to be targets for the so-called "white collar" crimes of false billing and other fraud, counterfeit money exchange, and theft by employees. The theft of personal items belonging to staff and patrons also may be a problem in some areas. As we shall demonstrate later, it is the unusual library that is free of all crime and disruption.

While property crimes against the library are the most common types of offenses, they may not be the most feared. Crimes against persons evoke strong reactions from those involved or concerned. Even when a library is free from personal crimes, the anticipation of a possible episode can be devastating to employee and patron morale.^[28]

Alan Jay Lincoln presents the results of the Library Crime Research Project in his article *Patterns and Costs of Crime*.^[29] This was a three-year study of the crime and disruption patterns in public libraries in all fifty states. It was a broad study designed not only to assess problems of crime and disruption but also to identify many of the conditions that facilitate or help to control these problems. The survey questions covered a variety of topics including 1) characteristics of the library and community; 2) descriptions of patrons and patron use patterns; 3) experiences with eighteen different types of crime and disruption; and 4) direct and indirect costs of crime including the use of security equipment and procedures. A total of 2,920 surveys were distributed to a sampling of the public libraries listed in the *American Library Directory*, and the 1647 surveys that had been returned by August 1983 were analyzed.^[30] In regard to theft of library materials, four kinds of theft were measured. These were book theft, which was the most common offense reported, reference material theft, theft of equipment, and other theft. Eighty percent of the responding participants reported at least one episode of book theft, and the majority of these involved six episodes.^[31] The results of this survey are outlined in the tables compiled from this study. (See Leab and Leab, Table 1, p. 71; Table 2, p. 73; Table 3, p. 74.)

The prevailing attitude in the past was that a theft should not be publicized to any outside authorities. This practice is no longer seen as ethical in the professional or library world. Virtually all institutions, large and small, have experienced theft problems.^[32] Efforts to keep thefts quiet sometimes led some institutions to take peculiar

measures to recover their stolen items, such as buying back at public auction the letters and other documents that had been stolen from them previously, rather than approaching the auction house and proving their ownership of the documents and requesting their return.

Instances of library theft continue to be reported by libraries throughout America, whether it is committed by staff members or visitors. Staff members have been reported to removing not only collection materials from the premises, items that have been accessioned and catalogued, and items that have not been fully accessioned and processed such as books, compact discs (CDs), and DVDs but also cash from fines collected or benefit book sales and office supplies.^[33] An instance of theft by a visitor includes the case of E. Forbes Smiley III, a map dealer and collector who was sentenced to 42 mo in prison by U.S. District Judge Bond Arterton on September 27, 2006, and was instructed to make a payment of \$1.9 million in restitution to the antiquarian booksellers and collectors he defrauded.^[34] Mr. Smiley had admitted to purloining 97 maps over an eight-year period from various libraries including the New York and Boston public libraries, Chicago's Newberry Library, Yale University, Harvard University, and the British Library.^[35] Mr. Smiley was attributed with stealing 108 maps, but the total number of missing maps from those institutions is 256. Mr. Smiley was sentenced to forty-two months and he served three years and six days. He officially earned parole on January 17, 2010.^[36]

The Wisconsin Historical Society was the site of a brash break-in when Matthew Brooke smashed the glass bookcase containing the bound volume of the *Pennsylvania Evening Post* containing issues dating to January to April 1777. Although the volume is valued at \$3000–\$5000, the explanation for the crime offered to the court by Mr. Brooke when he was charged in September of 2005 was that he wished to read an article about a historical figure named William Hill, not to profit from the sale of the item.^[37] Digital recordings are also of interest to library patrons as well as library staffers, as illustrated by the case of Binh Huu Hoang who pled guilty to first-degree theft for stealing \$3000 worth of CDs and DVDs from the Multnomah County Library (Oregon). Mr. Hoang was banned from the library and sentenced on July 28, 2005, to three days in jail, three years of probation, and 160 hr of community service.^[38]

Electronic articles available from libraries by purchase or subscription and personal data are targeted by cyber criminals around the world. The National Terrorism Advisory Board reported that Chinese hackers claimed to have exploited the City College of New York Library Proxy Server, downloading 25,000 e-mails and passwords. This incident occurred on September 16, 2013, and was reported to the City College of the New York Information Technology Department on September 30, 2013. The Information Technology Department subsequently shut down the City College of New York Library Proxy Server

without notifying either the chief librarian or the library computing manager. This server facilitates off-campus access for members of the City College of New York community to electronic material including database subscription articles and electronic books. There was no evidence that the Library Proxy Server was compromised. Proxy Server access was subsequently restored.^[39]

These and other motivations for library theft have been noted in the past and continue to be reported. The reasons for library theft listed in the 1971 doctoral thesis by Stephen Glen Poland, "Characteristics, Behaviors and Attitudes of Male College Students who have Committed Theft," were

1. Acquisitive vandalism
2. Tactical vandalism
3. Ideological vandalism
4. Play vandalism

An instance of tactical vandalism is presented as a case study by Bruce Shuman where the perpetrator, a law student, tried to borrow a reference work *Black's Law Dictionary* only until the end of the term from a public library branch because the competition for access to this work was so great among his classmates that he felt he needed his own copy because he was determined not to fail law school.^[40] An instance of ideological vandalism was reported by the San Francisco Public Library.^[41] An instance of vindictive vandalism, not to a library's physical assets, but to its financial assets, was perpetrated by a former employee, the information systems manager, whose actions were all the more insidious because this individual entrusted with access to the computing systems and network, the detection of the implanted program was all the more difficult to detect prior to the creation of the damage to the personnel, payroll, vendor, and circulation records. This computer programmer was convicted in Fort Worth, Texas, in 1998 of inserting a computer virus into his former employee's system that wiped out 168,000 records. The virus activated two days after he was fired, similar to a time bomb waiting to perpetuate the sabotage.^[42] An instance of play vandalism by several teenagers was reported by the Pennsauken Free Public Library (New Jersey) when they threw books and began yelling, creating a chaotic scene for fifteen to twenty minutes while there was a power failure. Order was restored after the emergency lighting activated and police arrived on the scene.^[43]

Libraries that have been perceived in the past as safe places to work or study have become sites for crimes of assault, equipment theft, and electronic data tampering or deletion, as mentioned earlier. Some of these assaults have included instances of rape^[44] or other bodily harm causing death.^[45] The murder of a librarian in Georgia brought home the issues of workplace safety. The victim was working alone in a small-town library in 1993. The

16-yr-old youth arrested for the crime stated that the motive for the crime was the desire to obtain the staff member's expensive jewelry.^[46]

Other threats to library property and visitors have been reported, demonstrating that libraries are not isolated from these dangers that are present in the current environment. Bomb threats^[47] and the concerns left in the wake of the shootings at the Virginia Tech on April 16, 2007,^[48] have left library managers considering installing metal detectors or instituting patron searches as they enter the library to prevent the admission of weapons into the facility in addition to the search of patrons or their belongings as they leave the library to prevent the unauthorized removal of materials.

With regard to the safekeeping of digitized information, librarians have to countermand intrusion from two constituencies, the government and criminals that might be computer crackers or hackers. With regard to the former, in the wake of the Patriot Act, patron records regarding activity and circulation have to be reprogrammed in order to prevent unnecessary inspection of such records. The massive flow of partially encrypted data across networks designed to allow for the unhindered flow of digital information potentially enables the criminal element access to data in order to perpetuate identity or financial theft.^[49]

By following the guidelines mentioned earlier, and implementing the sound security practices they advocate, hopefully thefts of library materials will be prevented by all but the most determined professional criminals. Good basic security and preservation policies should be practiced, such as marking valuable materials so that proof of ownership can be established if they are stolen, maintaining accurate cataloguing and inventory records so that an accurate report of what has been determined to be missing can be filed in case they are stolen, and keeping copies of those records that can be made available in order to prove ownership. Only by continual maintenance of accurate inventory, cataloging, and shelf list records can the theft of materials be determined with precision, whether it was by a patron or a staff member. Accurate record keeping is especially important for archival repositories, which include the maintenance of accurate inventory records, particularly the calendars of papers for the sets of papers in the collection, retention of the paging call slips with the name of each patron who requests materials, and of the registration forms filled out by the researchers. The paging slips are useful when items are discovered to be missing, and it can be determined more easily who may be the culprit. It has been suggested that each folder should be inspected or weighed by a staff member before archival materials are turned over to a patron in order to prevent the patron from being able to claim that those materials were not in the folder when it was given to them for use and that they are not responsible for any missing items.

In order for the library and archival profession to assess the problem of the theft of materials, to prevent further thefts, and to recover their materials, the scope of this problem must be determined accurately. A standardized computerized national database, such as the one that had been proposed by OCLC was a first step. Only with accurate reporting can overall annual or regional trends be determined. Institutions might be able to take preventive measures based on the emerging pattern, perhaps microfilming their collections of letters by Franklin Roosevelt if they seem to be the target for possible theft or placing volumes of illustrated botanical texts in closed stack areas if they are being mutilated in libraries in other parts of the country. Greater efforts to microfilm or digitize as much manuscript material in archival collections as possible should be undertaken because the replacement film copy reduces wear on the originals and provides documentation of proof of ownership if they are stolen, and if the master microfilm is stored off-site, the film can be a substitute for the originals if they are permanently lost or destroyed due to fire or flood.

IMPORTANCE OF GOOD COMMUNICATION WITH BOOK DEALERS

Open links of communication to the community of book dealers have been instrumental in the recovery of several of the items stolen from the Columbia University Rare Book and Manuscript Library. This theft was first discovered on July 5, 1994. The next day, on July 6th a list was compiled that went out on *ex libris*, to the ABAA network, to *AB Bookman*, and to the art theft networks. This list was subsequently updated to include the twenty-two items finally posted, valued at \$350,000. Descriptions and photographs of some of the stolen items were published in *IFAR Reports* over the next several months. In June of 1995, Jean Ashton, the director of the department, was about to send the list to the book dealers in the secondary market when they got a break in the case with an arrest.^[50]

When the theft of the seventeen rare manuscripts was originally discovered in July 1994, it had been speculated that it had to be an inside job. However, when the Dutch police arrested a suspect in Amsterdam on June 7, 1996, they found a convicted forger from Yonkers with two fake passports and a fake Columbia University identification, according to Federal agents.^[51]

The arrest, prosecution, and subsequent sentencing of Mr. Daniel Spiegelman (aka Mr. Kikabidze) brought a certain sense of relief, particularly since he subsequently told the authorities where some of the stolen items were stored, in safety deposit boxes in various locations in New York City and State. The items that were recovered—including two fifteenth-century *Books of Hours*, the historical chronicle from Caesar to Charles VI, a nineteenth-century Koran, a papal letter written in 1202, and documents bearing

signatures that appeared to be those of George Washington and John Adams—were all intact. There were seventeen codices taken, including European manuscripts produced in Europe from the thirteenth to the sixteenth centuries, and eight of these have not yet been recovered. There were twenty-three document sets taken and seven of those have still not been recovered. Some of the outstanding documents include two boxes of papers from the Thomas Alva Edison collection. The removal of leaves or miniatures by the thief for separate sale was the greatest fear of Jean Ashton and of those investigating this case. This fear was realized when the nine-volume Blaeu atlas was recovered, and it was determined that more than 250 maps had been cut out of the atlas set. As Jean Ashton explained at the Fatico Hearing for *United States vs. Spiegelman* on March 20, 1998, there was a five-year loss from 1993 to 1998 of scholarship, while the students of Columbia University would not have had the opportunity to be exposed to the materials that had been stolen by Mr. Spiegelman. The complete experience of intellectual examination continues to be curtailed because not all of the items have been recovered and sixteen of the stolen items may never be recovered such as the copy of the *Nuremberg Chronicles* that Mr. Spiegelman admitted to selling in Europe. This loss to scholarship is incalculable.^[52] The felon never named any accomplice.^[53]

Mr. Spiegelman was extradited to the United States. Law enforcement officials theorized that he tried to hold some bargaining chips to better his position since he must have realized that it is not good to go to prison for a long time. The authorities had him extradited to the United States for prosecution (something that Mr. Spiegelman tried to prevent; attorneys from the U.S. Attorney's office traveled to the Netherlands to argue for his extradition, which was scheduled for December 21, 1995), particularly since any statements he made in Holland where he was held were not valid in U.S. courts. In November 1997, Mr. Spiegelman was in custody awaiting trial. A prior plea bargain was retracted. The defendant gave information relative to his selling of maps and books in Paris. This information was forwarded to the French authorities who were unable or unwilling to further the investigation or recovery of the items.^[54]

He was turned in to the authorities and to Jean Ashton by three book dealers in Germany, Switzerland, and the Netherlands who called her and Detective Kalafus to notify them that the pieces had appeared on the market. Detective R.J. Kalafus was a 30-yr veteran of the New York City police force assigned to the 26th Precinct, who investigated cases of theft from three of the Columbia University Libraries. The dealers told Jean Ashton that a man calling himself William Taylor offered to sell a set of rare manuscripts that contained several pieces missing from the Columbia University Libraries collection. The suspect showed the dealers photographs of one of the *Book of Hours* and of another manuscript he also offered

for sale for 70,000 Dutch Guilders (about \$44,500). One of the dealers in Amsterdam agreed to pay 60,000 guilders. When the man returned with the merchandise, he was arrested because the authorities had been contacted in the interim.

Judge Lewis Kaplan sentenced Daniel Spiegelman in April of 1998 to 60 mo in prison, 3 yrs of supervised release, 300 hr of community service, and restitution of \$314,150 for the theft of works valued at \$1.3 million. Judge Kaplan imposed a lengthier sentence because the magnitude of the crime meant the deprivation “of a generation of scholars and students of the irreplaceable raw materials by which they seek to discern the lessons of the past and help us to avoid repeating it. That’s what differentiates [this] offense from a simple theft of money or other easily replaceable property.”^[55]

Mr. Spiegelman’s activities did not end there. In October 1999, Jean Aston received a call from an autograph dealer in Greenwich, Connecticut, Basil Panagopolous, because he had been offered some papers of Thomas A. Edison and Presidents Thomas Jefferson and James Monroe that Mr. Panagopolous suspected were from the Columbia University Libraries collection. Apparently Mr. Spiegelman had escaped from his work release program in Manhattan, retrieved the materials from an unknown location, and crossed state lines in an attempt to sell them. The alertness of the manuscript dealer led to Mr. Spiegelman’s rearrest and an additional twenty-four-month sentence. This sentence was imposed by Judge Loretta Preska on May 24, 2000, followed by an additional three years of probation. It is clear that Mr. Spiegelman is still aware of the location of materials taken from the Columbia University Rare Book and Manuscript Library that have never been recovered.^[56] Mr. Spiegelman served his sentence of a little more than six years in custody and was released on July 19, 2001.^[57]

This type of crime should be taken more seriously as the Stephen Blumberg case, in which thousands of volumes were eventually recovered, illustrates. Valued at a total of \$5.3 million, the materials were taken from 327 public, private, and university libraries in 45 states over a 20-yr period. This case and others highlight the value of the materials that were stolen. Stephen Carrie Blumberg, born in 1951, was arrested on March 20, 1990, and sentenced to 5 yrs in prison. He was released on December 29, 1995, after serving his term. He was not fulfilling the terms of his supervised release or parole and subsequently surrendered to authorities and was rearrested on January 5, 1996. He was subsequently held in a federal prison hospital mental health facility in Rochester, Minnesota, for psychiatric evaluation and released in June 1997.^[58] His bibliokleptomania led him to accumulate 11,000 books, letters, and manuscripts, which filled his house in Ottumwa, Iowa.^[59] His obsession with books grew out of his earlier collecting manias for doorknobs and other such hardware items.

As a notorious recent case, it dramatizes the problem of library theft for the library community,^[60] as do others. The library community was aware of the activities of Stephen Blumberg prior to his arrest, but due to poor communication among libraries, he eluded apprehension until an informant helped the federal authorities. Stephen Blumberg obtained false identification and passed himself off as Professor Matt McGue, a faculty member of the University of Minnesota. Although he was arrested and convicted of trespass at the University of California-Riverside library and of possession of burglary tools under this identity, he apparently continued his activities until his subsequent arrest even though a report of this incident had been published in *Library & Archival Security*.^[61] The search of his premises by the FBI revealed materials reported missing from more than 327 institutions in 45 states and Canada. He was convicted on January 31, 1991, in U.S. District Court of all the felony counts with which he had been charged, including conspiracy to transport stolen property across state lines, two counts of transportation of stolen property, and one count of possession of stolen property. He had pleaded insanity to the charges.^[62] Although he had been arrested previously for pilfering materials from a library under an assumed name, the pattern of his activities was not revealed to the library community as a whole until his arrest, trial, and conviction. This case has underscored the need for an accurate national database to record missing materials from libraries so that if a pattern of these activities is present it can be revealed sooner and librarians can be alerted to the possible danger to materials in their collections.

As various libraries began to discover that books were missing due to Mr. Blumberg’s activities, the ACRL Rare Book and Manuscript Section Security Committee began in 1987 to gather a single listing of library thefts, the “Incidence of Theft.” A member of the committee volunteered to keep it up to date and to issue a revised version prior to each annual ALA meeting. A document of one page in length grew to 22 pages by 1995, highlighting the problem and the exchange of information among libraries.^[63]

TREASURES MISSING FROM THE LIBRARY OF CONGRESS

The Library of Congress, the de facto national research library, has been plagued with problems of theft and mutilation of their materials since 1992.^[64] As a response to this problem, procedures were into place at that time, including closing the stacks whereby the library beefed up security by barring all but essential personnel from the collections and an agreement that it would notify both the U.S. Attorney’s office and the FBI of any “property offenses.” Despite the assurances of James Billington, the Librarian of Congress, when he stated in October 1994 that security was “one of the three top institutional

priorities of the library,” Deborah Maceda contended that the ransacking of the library’s collection continued unchecked. Deborah Maceda was the library’s Protective Services Office staff member who was removed from office on July 12 for submitting notification of missing materials. She compiled a list in June 1995 of mutilated documents that filled 68 pages, showing that 26,985 plates are known to be missing from publications valued at a total of \$1.75 million. Former Senator Connie Mack called for a General Accountability Office investigation into security lapses and the magnitude of the losses. Senator Mack, Florida Republican, as former chair of the Appropriations Subcommittee that oversees the library, had the authority to call for such an investigation, especially after receiving memos and reports of these losses from Deborah Maceda. An aide to Senator Mack said other committees with jurisdiction over the library were notified.^[65] Hearings investigating these allegations were held before the Joint Committee on the Library of Congress and the Appropriations Committee on November 29, 1995.^[66]

Sometimes cases of theft can even lead to murder. A robbery of 89 ancient manuscripts from the Russian National Library in St. Petersburg dating from the thirteenth to the eighteenth centuries was posted on the ABAA Stolen Book List by Vladimir Zaitsev, the library director. Dmitry Yakubovskiy, a controversial lawyer and alleged former KGB agent with the nickname “General Dima,” was arrested after being detained on December 20, 1994, on suspicion of complicity in the theft of those eighty-nine manuscripts worth about \$100 million from St. Petersburg’s National Library. He had emigrated to Canada and then returned to Russia prior to his arrest. According to reports, Mr. Yakubovskiy had very good relations with many top Russian officials. Yevgeny Melnitsky joined the team to defend Mr. Yakubovskiy in August 1995. The attorney, Yevgeny Melnitsky, 49, was found by his driver in his apartment on September 25, 1995, with his throat cut and his head bludgeoned, according to police detective Marina Gurina.^[67] Authorities said they found no sign of forced entry or evidence of anything having been taken from the apartment. Police said they were investigating a potential link to his work in defending the controversial lawyer Dmitry Yakubovskiy. Mr. Melnitsky had important documents related to the case that were “dangerous to some people,” one of the other Yakubovskiy defense lawyers said, on condition of anonymity.^[68] On September 20, Melnitsky had been elected chairman of a District Electoral Commission. The Electoral Commission does not believe that his murder has anything to do with these activities, but rather with the legal case.^[69]

REPLEVIN

As mentioned earlier, sometimes libraries have taken elaborate measures to recover their stolen items. In the case of

the documents that were stolen from three Texan institutions, proving their prior ownership to the satisfaction of the Parke-Bernet Galleries would have been relatively easy since these letters had been referred to in publications concerning early Texas history, and the source for these documents had been cited as these respective repositories. Members of the staff at the Texas State Library did not exercise their right of replevin or recovery by a person or institution of goods claimed to belong to them, on the promise to test the matter in court and give the goods up again, if defeated. Cataloging records alone formulates a weak case; other documentation should be produced to prove ownership definitively in court, such as microfilm of the manuscript items, a citation in an exhibit catalog, or credit to a repository in the publication of a set of papers. Forty-two items among the lots sold in an auction held at Parke-Bernet Galleries on November 21, 1967, belonged to the Texas State Library, the University of Texas, or Rosenberg Library in Galveston. Representatives for the University of Texas were present at the sale and bought back many of these items, which were returned to the Texas State Library, having been “recovered” in New York.^[70]

SUGGESTIONS FOR PREVENTION

Spend the Money on Security Systems and Trust No One

Detective R.J. Kalafus, as mentioned earlier, has investigated cases of theft from three of the Columbia University Libraries, and he offers two main points for the prevention of this type of crime: spend the money on security systems and trust no one. Spending the money for security systems, whether they be alarm systems or video surveillance, may be difficult in this time of budget cuts, but the consequences may be more costly. When choosing a security system, it would be wise to consult with a law enforcement agent to get a recommendation. Something else to keep in mind is to limit the number of keys issued to staff for access to secure areas. Only a limited number of those keys should be issued to authorized personnel.

In the course of his investigation of the theft from the Columbia University Rare Book and Manuscript Department, following the initial report of the theft, Detective Kalafus visited the department to survey their security system and arrangements. He assessed their alarm system to be fairly good, and any loud noise will set it off, even the sound of a closing elevator door. To help him with his inquiry, he was given six book storage boxes by staff members to take with him for examination. He found it ironic that as he was leaving with these boxes, no one stopped him or questioned him regarding what he was doing with them, it was not until he stopped to light a cigarette that half a dozen people suddenly appeared to

tell him to put it out. He has determined that there were too many keys issued to various staff members.

Another thing to remember is trust no one. When security procedures are implemented, they should be applied consistently. As mentioned earlier, the Library of Congress implemented new procedures in 1992 which were not followed, resulting in very little change in the numbers of mutilated volumes on the shelves.

Use Consistent Security Procedures: Search Everyone

When security procedures are implemented, they should be followed consistently. At the very least, everyone should pass through a security checkpoint upon exiting. If it is determined that someone should be subject to a search, which may be objectionable, it should be explained gently but firmly that this is for everyone's benefit, since whenever any materials are permanently removed from a library collection, it detracts from the overall integrity of that collection and diminishes our overall cultural heritage.

Of course, no alarm system designed to alert one to an outside break-in can protect the collection from an inside theft. Terry Belanger, speaking at the 1983 Oberlin Conference on Theft reported in *Library Journal*, estimated that "25% of the thefts are inside jobs committed by students, professors, librarians, staff members, and janitors, rather than professional criminals."^[71] Ronald Lieberman, former chair of the Security Committee of the ABAA confirmed that "insider theft is a problem."^[72]

Two cases of insider theft that have come to light occurred at the University of Georgia library in Athens and at the Rosenbach Museum and Library in Philadelphia. Materials belonging to the rare book collection including more than a thousand rare maps, manuscripts, and folio places, estimated as being worth over \$1 million, were discovered to have been stolen over a period of several years. The theft was discovered when it was determined that items were missing from the map collection in June of 1986. During a subsequent inventory of the collection, the list of missing items was expanded to include a 1776 British atlas, and a set of nineteenth-century botanical folio prints, *Les Liliacees* published in eight volumes, and duplicate copies of various items in the map collection. Thomas E. Camden, the head of the Hargrett Rare Book and Manuscripts Collection, noted that their "biggest problem is trying to identify the materials as ours once they have been located," since many of the items were not marked.^[73] A former employee, Robert "Skeet" Willingham Jr., resigned on October 15, 1986, after an investigation into the suspected thefts had already begun in June of 1986. He became the prime suspect for these thefts after his home had been searched four separate times by campus police who found materials that could have come from the library in the course of those searches.

The campus police filed an affidavit in connection with these searchers and stating that "It is known that [Willingham] has sold property belonging to the University of Georgia."^[74] Thomas Camden, commenting on this insider theft problem, noted that the University of Georgia library with closed stacks has had few problems with theft by patrons, but added that "I don't know of any system that will protect a library from within."^[75]

The case of the missing materials at Rosenbach Museum and Library in Philadelphia was more insidious because in the course of their investigation it was revealed that inventory records had been purposely altered by the perpetrator of the thefts to cover up the fact that he was pilfering documents from their collection and selling them through book and manuscript dealers. When Ellen Dunlap took over as director of the Rosenbach Museum and Library in 1983, she had no idea that she would inherit a serious problem as a result of the activities of the former director, Clive Driver. Not only had he worked there for twenty years and served as director since 1965, he had actually been allowed to live on the premises.^[76] When Dunlap took over as director in 1983, an investigation of a file marked "Missing Items" was inconclusive. A more serious problem emerged when the Rosenbach was contacted by telephone on February 26, 1987, by Mary Jo Kline of Sotheby's inquiring about a 1790 John Adams letter to John Trumbull that was about to be consigned to auction. The staff of the Rosenbach were unable to establish if the Rosenbach had ownership of this document or not, particularly since the inventory book had been emended in blue pencil, creating doubt as to whether it had been deaccessioned after 1959. During the course of the continuing investigation into this mystery, Mary Jo Kline revealed that the current holder of the letter was a Massachusetts dealer, Paul Richards. Paul Richards in turn identified the person who had sold him this document as Clive Driver, who had recently retired nearby.

When this revelation was made, the alarm bells went off and Ellen Dunlap had to go into action. After conferring with their lawyer and members of the board, changing the locks, and contacting the insurance agent, she filed a civil suit in federal court to seek return of the Rosenbach's property.^[77] In November of 1989 the civil suit was settled with a provision for the return to the Rosenbach of fifty-eight documents disseminated by Clive Driver. Criminal charges were also filed against Driver who was convicted on felony charges and sentenced to pay a \$50,000 fine and serve 3 years of probation that includes 2,000 hr of community service for the interstate transportation of an historical document.^[78]

The case of the materials stolen from the Rosenbach Museum and Library by Clive Driver that were sold to the Massachusetts dealer, Paul Richards, and the case of the materials stolen from the Columbia University Rare Book and Manuscript Department by Mr. Spiegelman both illustrate the point that the staff of libraries and archival

institutions should foster good relations with book and document dealers so that they will be more likely to notify the authorities and those institutions known to them as collecting books or documents concerning a particular subject category when they are offered materials for sale that are related to that topic. This would not only help in the recovery of stolen materials but also could be a means of increasing the holdings in a collection within a certain subject area since the institution could consider purchasing the material from the dealer. Reporting missing items to ABAA and getting it listed in the column published in *Antiquarian Bookman* is only part of the recovery process, and staff members at institutions should make direct contact with those dealers who specialize in materials relevant to their collections. Also, the curator of a special collection or rare books collection in a library should be familiar with the current market value of materials in the collection by consulting dealer catalogues and listings of prices paid in an auction house sale of items comparable to those in the collection.^[79]

Microfilming

Mimi Bowling, former curator of the Manuscript Department at the New York Public Library, suggests another approach—microfilming. Microfilming manuscripts reduces the wear on the originals while providing an acceptable substitute for most researchers. As she explains it, “Good security measures are good preservation practice for anything valuable. Be sure not to [have it] handled more than [it] needs to be, limit [the] use to film [as] one solution.”^[80]

Also, in keeping with the idea of limiting the number of keys that are issued, at the New York Public Library Manuscript Department, only a few members of the staff have been issued electronic key cards that open the containerized steel shelf units, and the system records the key code used to operate it and the time that the shelves were opened. Since the key codes are each linked to a specific staff member, the access to these stacks can be monitored.^[81] Although it is possible to withdraw materials from one area of the stacks and place them in another stack area, if accurate shelf lists are maintained, it should be quickly apparent that the materials are out of place.

Mark Materials and Use Colored Photocopy Paper

The practice of marking manuscripts and other library materials has been the subject of controversy within the library profession. Each set of guidelines promoted by the RBMS Security Committee give specific instructions as to how to mark these materials in such a fashion that they will not be disfigured to such an extent that they will be unusable by researchers or prohibit them from being exhibited by the institution that owns the material. The Library of Congress recommends the marking of paper

manuscripts with a proof of ownership and will even provide upon request bottles of ink that can be transferred by means of a five-point ownership stamp. This ink has been tested for its resistance to removal by application of solvents or bleaches and for its slightly alkaline pH of 7.0 to 7.5, and it is nonmigrating to other pages and nondestructive to the paper.^[82] At the Oberlin Conference on Theft in 1983, Katherine Leab of BAMBAM recommended the establishment of a national registry of library markings.^[82] The importance of marking archival materials with a distinctive stamp denoting ownership and keeping track of the different designs for these ownership marks used by the institution was emphasized again by Katherine Leab.^[84] Ronald Lieberman, the former chair of the Security Committee of ABAA, also recommends the use of marking library materials as an aid in proving ownership and for deterring theft.^[85] However, he does not neglect to mention that cancellation of these ownership marks is equally important and marking the materials as “WITHDRAWN” or indicating that they were deaccessioned in some fashion. Of course, the cataloging and inventory records should also indicate if certain items were deaccessioned.^[86] Lieberman also mentioned that accurate inventory records are important because then one can be more “aware [of] what is in the collection so that it will be more apparent that [any materials are] missing.”^[87] Those inventory records are vital for proving ownership and are an aid in recovery as well.

These guidelines regarding the marking of library materials for security reasons state that all materials should be marked. This includes Medieval and Renaissance manuscripts, incunabula and early printed books, single-leaf manuscripts, broadsides, prints, maps, and printed books. The process of adding an ownership mark to library materials at the time of acquisition could be incorporated into the initial processing of materials, but the retrospective marking of a large collection is a difficult undertaking. Such a project has to be planned carefully so that it is implemented in an orderly way to make the best use of staff resources and time and of money from the budget.^[88] Considering the constraints placed on most institutions by limited budgets, it is unrealistic to expect that most of them will undertake such a procedure. It is unlikely that institutions will try to mark the contents of their entire collection; therefore efforts should probably be directed at those items that have been appraised to have a high value because they are likely to be targeted by thieves. The marking of library materials either with an inked stamp, a perforated pattern, or an embossed pattern also violates one of the principles of conservation, not to carry out any procedure on library materials, which is irreversible. Even though this may be the case and such marking can detract from the aesthetic or exhibition value of the materials, Katherine Leab believes that archivists should spend more of their time marking the manuscripts in their care. Katherine Leab has also suggested for

manuscript collections that make photocopies of their materials available to researchers on demand should make the photocopy on colored paper so that the patron cannot substitute the copy for the original document when the folder is returned. The copy should also be clearly marked as such by the institution.^[89]

The preparation of manuscript or other library materials for microfilming would take about the same amount of time as retrospectively marking them, because in each case the materials have to be physically handled by staff members for a period of time to carry out either procedure. Since microfilming is usually not destructive to the original materials and does not detract from their aesthetic value nor is it an irreversible procedure, it is a better security option. In addition, the microfilm and the records stating that the materials were scheduled for microfilming are additional documentation that can prove ownership if the originals are stolen.

BETTER AWARENESS: LOBBY STATE LEGISLATURES

Another program that can be undertaken by institutions to help prevent library theft is to lobby for stronger statutes for the conviction and prosecution of library crimes. Hopefully, if criminals are aware that they will be prosecuted under strict legal codes if they are caught, they will think twice before perpetrating such crimes. The Society of American Archivists sponsored the drafting of model legislation in 1975 and lobbied the law enforcement community to enact the proposed legislation. A law passed in Virginia that contains provisions that can be effectively be enforced served as the model. This legislation (Virginia Code SS42.1-72/1.74.1) defines the crime of mutilation of library materials as a class I misdemeanor. The concealment of a book or other library material while still on the premises of the library or removing it in a concealed fashion is defined as larceny. This is highly significant because it prevents a prospective thief from claiming that he forgot to return the manuscript or book or that he meant to have the material charged out. This legislation also grants the archivist or librarian immunity from civil liability for actions arising out of the detention of a suspect. However, if a patron is detained due to suspected activity that may constitute theft, the library staff should handle the situation carefully. The person can be detained on the library premises preferably by two staff members, one of them can be a member of the institution's security force, and no action should be taken until municipal law enforcement officials arrive.^[90]

How seriously a municipality takes library theft can be reflected by the punishments allowed under local laws. Massachusetts passed a law in 1990 allowing for fines of up to \$25,000 and 5 yrs in jail for stealing library materials. The need for such a strict measure was demonstrated

by one small-town library serving a population of 23,000 was losing \$12,000 worth of books each year. It was estimated that throughout this Commonwealth, public libraries had material losses of \$1.1 million yearly.^[91] It is amazing that it took so long for such a statute to be enacted. During the 1930s a ring of book thieves visited libraries throughout Massachusetts and other eastern states by either simply taking volumes off the shelves and hiding them in their overcoats or checked them out as library patrons under an alias and never returned them. They removed or disguised any library ownership marks and sold them to secondhand book dealers on Fourth Avenue in New York.^[92]

Some locations abroad, such as Nigeria, take a rather serious view of such infractions. A conviction of theft of library property can earn the perpetrator up to seven years in prison, if the magistrate sees fit to impose such a sentence.^[93]

SECURITY DEVICES

One widely utilized prevention measure that has been taken by libraries throughout the United States is the installation of electronic and other mechanical security devices. Some of these security devices detect intrusions on the premises when they are closed for operation to personnel and the public. They can also detect intrusion into secured areas while the institution is open for normal operations. These magnetic sensors, pressure sensitive mats or sensors, and photoelectric or ultrasonic beams can all activate an alarm system when they are triggered, either an alarm audible on the premises that can frighten away the intruder or an alarm that is silent at the premises but that activates a signal at another location, such as a nearby police station or at the office of a contracted security service.

A security system that has been installed in libraries throughout the country since the 1970s is the security system that electronically surveys patrons as they exit to detect if they have any improperly charged out library materials. For these systems to work, treated detector tags must be placed in each material in the library collection, and when these tags are taken past the sensing screens, usually located near the circulation desk or at the exit point for the library premises, an alarm will sound if the materials are not charged out properly. These detection tags are placed in the library materials when they are initially processed at the time of acquisition.^[94] Such systems are not foolproof in this age of ever more sophisticated technology. Tattle tags can be silenced with a device that could be purchased for \$17.99 at Radio Shack.^[95] A tattle-tape system is difficult to implement in archives in any case because the materials are often single leaves that make it more difficult to attach the tags to the leaves than it would be to attach them to bound volumes. The number

of single-leaf items in an archive poses a similar problem to that of marking manuscripts, and it is very difficult for an institution to allocate the amount of staff time that would be needed either to attach the special tags or to mark the individual leaves. Also archival materials never circulate, so it would be better for the institution to direct their resources to monitoring the use of the materials on the premises.

The recently introduced technology for the library security market, radio-frequency identification, offers an alternative to magnetic strip tattle tags and barcode identification tags. The smaller tag size makes it possible to attach them more easily to individual document items. However, the greater cost per unit, around \$0.65–\$0.75 each, versus about \$0.02 for barcode tags has prevented a large penetration into the library market. In addition, the feature allowing for more universal tracking of the item and potentially of the user who has the item in his or her possession has raised questions regarding privacy invasion of the user. Until the privacy issues and cost factors regarding the per unit cost and the cost of interfacing the technology with circulation transactions can be standardized, many libraries are likely to remain with barcode identification systems.^[96]

Careful planning and layout of the reading room where archival materials are used can aid the staff members to accurately monitor how materials are being used and if they might be concealed by a patron. What is of primary importance is to have at least one staff member present at all times. The desk area where the staff member is positioned should be elevated and have a clear line of sight to all work areas at the reading tables. If additional staff members have offices located nearby, glass walls can be installed so that they can periodically assist in the monitoring effort. Strategic placement of two-way mirrors and of closed circuit television cameras can be included to aid the staff member in surveying the activities in the reading room (see illustration on page 5 in Timothy Walsh, *Archives and Manuscripts: Security*. Chicago: Society of American Archivists, 1977). Although it is difficult for the staff member to observe the closed circuit monitor and the patrons in the reading room and it may be too expensive to assign a member of the institutional security force to constantly watch the monitor, the presence of an active camera can be a deterrent to a thief, and the videotape is important evidence for the eventual prosecution of the perpetrator.^[97]

When someone is convicted of this type of theft, stronger sentencing should be implemented. As illustrated by the examples of the cases mentioned earlier, Stephen Blumberg, who has served his five-year term, and Clive Driver, who was sentenced to three years probation, including 2,000 hours of community service with a \$50,000 fine illustrate, this type of crime is not taken seriously enough. In yet another case of insider theft, Carol Ann Van Swearingen, a former librarian at Tremont

Road library in Upper Arlington, pled guilty to one count of theft for having nearly 6000 books and other materials in her home without library permission. For this crime she has been given two years of probation whereby she must seek counseling for her obsession with books, perform 160 hr of community service, and pay a \$2500 fine.^[98] However, some public libraries are adopting “get tough” attitude and are calling for help from their local police. The Rolling Meadows Library in Illinois now asks for police help when a patron has kept materials worth \$250 or more for a period of 60 days. A uniformed police officer pays a call on the recalcitrant patron and requests the missing materials and instructs them that they have to appear before a judge. This kind of enforcement of the Illinois law against library theft is getting results; about \$4000 worth of materials have been recovered.^[99]

COMMUNICATION AMONG LIBRARIANS ABOUT THIS PROBLEM

Members of the library and archival profession have also discussed the problem of what to do about missing library materials in meetings such as the one convened at Oberlin College in 1983 to discuss the problem of library theft in the wake of the thefts by James R. Shinn, who was apprehended in April 1981 by William A. Moffett, director of the libraries at Oberlin College. James Shinn was linked to the theft of \$750,000 worth of valuable books from the open stacks of some 40 libraries throughout the country.^[100] The Society of American Archivists has periodically sponsored discussion of this issue at a conference held in Detroit in 1979^[101] and at their annual meeting in September 1991, which included a panel discussion of insider theft of archival materials in the program. The panelists included Ellen Dunlap formerly of the Rosenbach Museum and Library; Daniel Traister of Special Collections at the Van Pelt Library, the University of Pennsylvania; and Robert Bazin from the Philadelphia office of the FBI.^[102] A Preconference Workshop on “Security in Archives and Manuscripts Repositories” was scheduled on September 12, 1992, as one of the activities associated with the annual meeting in September 1992 of the Society of American Archivists held in Montreal. Mimi Bowling, curator of manuscripts at the New York Public Library, and Richard Strassberg of Cornell University were going to lead the discussion. It was canceled due to lack of enrollment.

The various public and private libraries that have the responsibility for the safekeeping of materials for the public trust and to make them available for scholarship have formulated guidelines through professional associations as to what measures to take to prevent the loss of the materials in their possession and what to do in the event that any materials are discovered to be in fact missing and possibly stolen. The ACRL and the ALA have been

particularly active in this area. The Society of American Archivists sponsored the publication in 1977 of *Archives and Manuscripts: Security* by Timothy Walch that engendered discussion of the issue of library security within the archival and library professions by suggesting a basic checklist system approach for planning a security program.^[103] The ACRL approved a set of "Guidelines Regarding Thefts in Libraries" in 1988.^[104] The set of "Guidelines for the Security of Rare Book, Manuscript, and Other Special Collections" drafted by the ACRL Rare Book and Manuscript Section's Security Committee in 1982 and approved in June of 1990 are of particular interest to the archival profession.^[105]

These sets of guidelines suggest that a security officer should be appointed from among the staff members who will act as a liaison with the institution's legal counsel and security force as well as with the Security Committee, Rare Book and Manuscript Section, ACRL, and ALA. The security officer will coordinate the steps to be taken regarding the notification of outside organizations that materials have been discovered to be missing. The major reporting organizations for library thefts are the ABAA, BAMBAM, and the FBI if the value of the stolen materials is greater than \$5000, and there is reason to believe the items could be transported across state lines.^[106] Local and state police authorities should be notified in the event there is any criminal activity in a library, whether it is the theft of library materials or of cash from the fines box or in potentially serious cases when a patron is assaulted by another patron.^[107]

CONCLUSION

What can I say in conclusion? Take steps to plan for such a disaster just as for a fire or flood beforehand. Install security devices and implement consistent security procedures. Mark or microfilm or digitize the materials in your collection, especially manuscript materials. Foster good relations with law enforcement agents and book dealers; they are your best allies for turning in a suspect in case of a theft. Also, it is the responsibility of the director of any manuscript department to keep track of the market and have a sense of the value of the items in his or her care. If a theft does happen in your institution, the first thing you as a staff member in authority should do is to start a log of events, starting from the first day the theft is detected. Such a log may become useful for building the case against any suspects. Hopefully if perpetrators are caught and prosecuted under existing statutes and receive sentences that are more strenuous than community service, they will realize that the personal or monetary gain is not worth the risk, and libraries can turn their efforts to other areas, possibly promoting programs to serve their users and their community.

Museum Studies Program, Faculty of Information Studies, University of Toronto, Toronto, Ontario, Canada

Abstract

Theft and vandalism are two criminal acts that occur within museums and other cultural heritage institutions. This entry provides a historical context for art theft with an international scope, and highlights such famous examples as the thefts of the *Mona Lisa*, two versions of *The Scream*, and multiple masterworks stolen from the Isabella Stewart Gardner Museum in Boston, Massachusetts. Next, the complex definitions of vandalism, citing case study examples of Mary Richardson's attack on the *Rokeby Venus*, and Yuan Chai's and Jian Jun Xi's actions on Tracey Emin's work, *My Bed*. Finally, a discussion of museum responses to incidences such as these highlights the preventative measures and security devices that cultural heritage institutions employ to deter potential wrong-doers and protect the objects they hold in the public trust.

INTRODUCTION

As public institutions, museums, art galleries, and historic sites are professionally and ethically bound to protect and conserve their collections from all forms of deterioration, damage, and loss. The theft or destruction of any artwork or artifact is a collective loss for society, and as caretakers of these material goods, museums have an essential role to prevent these crimes from occurring. The International Council of Museums (ICOM) Code of Ethics describes the primary responsibility of museums "to protect and promote this heritage as well as the human, physical, and financial resources made available for that purpose."^[1] Museum stewardship includes intrinsic notions of "rightful ownership, permanence, documentation, accessibility, and responsible disposal."^[2] In short, they ideally ensure that all objects in their collections will survive for the benefit of present and future generations. Acts of theft and vandalism, therefore, pose very real threats to the proper functioning of all cultural heritage institutions.

Famous examples of theft provide a historical context for this type of crime on an international scale, and include such examples as the thefts of the *Mona Lisa* from the Musée du Louvre in Paris, France (created 1502; stolen 1911); two versions of *The Scream* from the Norwegian National Gallery and the Munch Museum in Oslo, Norway (created 1893; stolen 1994 and 2004, respectively); and multiple masterworks stolen from the Isabella Stewart Gardner Museum in Boston, Massachusetts (multiple

dates; stolen 1990). Vandalism varies more considerably in its levels of criminality, depending upon the intent of the action, and case study examples of Mary Richardson's attack on the *Rokeby Venus* (created ca. 1640s–1650s; vandalized 1914); and the instance when Yuan Chai and Jian Jun Xi jumped onto Tracey Emin's work, *My Bed* (created 1998; vandalized 1999), serve to illuminate the political and artistic motivations behind this behavior. Incidences such as these and many others have prompted museums to develop preventative measures and security devices to deter potential wrong-doers and protect the objects that they hold in the public trust. In addition, a host of international government and professional organizations designed to track stolen and affected cultural property have evolved, including the International Foundation for Art Research (IFAR) New York, International Committee on Museum Security (ICOM-ICMS) Paris, the Federal Bureau of Investigation (FBI) Art Crime Team Washington, the Metropolitan Police Arts and Antiques Unit London, the Interpol Art Theft Division Lyon, and others.

THEFT

Definitions of Theft

A variety of definitions are associated with theft, including moral, legal, and popularized types. In a moral sense, theft

is defined as the act of stealing; the unlawful or wrongful taking of property with intent to deprive the owner of his or her possession.^[3]

In a literal, legal sense the Criminal Code of Canada states that “An act of theft is committed by taking or converting anything, whether animate or inanimate, with intent to deprive, temporarily or absolutely, the owner of it, or a person who has a special property or interest in it. This also includes transformations to anything in such a manner that it cannot be restored in the condition in which it was at the time it was taken or converted.”^[4]

The U.S. Criminal Code specifically articulates a definition of theft in the context of museums: “Theft of a major artwork” refers to a person who

steals or obtains by fraud from the care, custody, or control of a museum any object of cultural heritage; or knowing that an object of cultural heritage has been stolen or obtained by fraud, if in fact the object was stolen or obtained from the care, custody, or control of a museum (whether or not that fact is known to the person), receives, conceals, exhibits, or disposes of the object.^[5]

In this description, theft is distinguished from acts of vandalism and forgery. Theft is usually intentional, with the criminal’s intent to take an object for trade, bargaining, or selling outright. The most common motive for theft from museums and cultural heritage institutions is financial gain. Whether sold illegally on the black-market, or used as ransom or leverage, art theft is a \$6 billion industry.^[6]

A Brief History of Theft in Museums

The history of art is laden with examples of objects changing hands under questionable circumstances. Issues such as wartime looting and the many problematic examples of repatriation are but two of a vast list of potential starting points for the study of such crimes; these particular issues are addressed in other entry (see entry on “Art Looting and Trafficking,” p. 272 for more information). A brief historical introduction here provides information on two key individuals inextricably linked with the history of art crime.

Adam Worth (1844–1902) is known as “the Napoleon of the criminal world.”^[7] He is most famously remembered for stealing a portrait of the Duchess of Devonshire by Thomas Gainsborough from the Thomas Agnew & Sons gallery in London, England (created 1787; stolen 1876). With the help of his accomplices, Worth stole the painting, which at the time had been sold at auction for 10,000 guineas, and was then the most expensive work of art in the world. Worth held onto the painting until just before his death in 1902, when he was forced to relinquish it due to financial reasons.^[8]

Author Simon Houpt frames Joseph Duveen (1869–1939) as a master opportunist, and one of the most successful art dealers of all time. Duveen, who is best known

for saying that “Europe has a great deal of art, and America has a great deal of money,” was a British-born entrepreneur who made his fortune by purchasing the collections of failing European aristocrats and facilitating their reselling to American industrialists seeking a means of class distinction. Although his methods were sometimes described as unscrupulous, Duveen nonetheless contributed greatly to the development of North American collections as well as the museum system in England, funding wings at both the Tate and National galleries.^[9]

Famous Cases of Theft in Museums

Although art crimes continue to occur at an alarming rate around the world, there are certain examples which illustrate the unfortunate history of events that mark the past. Three of the most recognizable instances of theft occurred in Paris, Oslo, and Boston in 1911, 1994/2004, and 1990, respectively. The thefts of the *Mona Lisa*, two versions of *The Scream*, and the masterworks stolen from the Isabella Stewart Gardner Museum, constitute ample illustrations for a succinct study of art theft from the last century.

The *Mona Lisa* was stolen from the Musée du Louvre in August 1911 by Vincenzo Peruggia, an employee of the museum. Peruggia, a carpenter by trade, had been hired to install protective glass cases around certain works, including the *Mona Lisa*, as a result of recent attacks by vandals to the museum. Peruggia removed the painting from its wall hanging after quietly emerging from a storage closet that he had hidden in overnight. He then proceeded to separate the work from its frame in a stairwell, placed the painting inside his coat, and walked out of the museum, which was closed that day. Peruggia kept the work in his apartment in Paris for 2 years, but was caught by police when he tried to sell it to the Uffizi in Florence, for the price of 500,000 lira. He was eventually convicted in court and served a sentence of 7 months and 9.^[10]

As a result of its disappearance, the *Mona Lisa* gained immense popularity and is recognized worldwide. Darian Leader, an author and psychoanalyst, postulated that Leonardo da Vinci’s *Mona Lisa* really only became famous after it was stolen. In his publication, *Stealing the Mona Lisa: What Art Stops Us from Seeing*, Leader states that “in the ensuing months [after the theft] composers wrote tunes about the Mona Lisa and its subject’s beauty; editorial cartoonists mocked police efforts to find her. . . .”^[11] Peruggia’s motives for the theft are not wholly clear, however during his trial he claimed that he had acted as a patriot, endeavoring to return an important piece of cultural property to its native Italy.^[12] His efforts to sell the *Mona Lisa* suggest that monetary gain was a motivating factor in the theft. Another theory proposes that Peruggia had been hired by Eduardo de Valfierno, an Argentine con man, to steal the work, and that Valfierno had planned to make forgeries of the artwork and sell them

across the globe to buyers who thought that they were acquiring the authentic *Mona Lisa*.^[13]

In a second, equally brazen theft, four men broke into the Norwegian National Gallery on February 12, 1994, and stole one of Edvard Munch's iconic versions of *The Scream* (1893), leaving behind a card upon which was written "thanks for the poor security."^[14] Prior to its theft, the painting had been moved to the ground floor of the gallery as part of the festivities surrounding the XVII Olympic Winter Games in Lillehammer (1994). Following a coordinated sting operation orchestrated by the J. Paul Getty Museum (Los Angeles, California) and the Metropolitan Police (Scotland Yard, London, England), the painting was recovered without significant damage on May 7 of the same year. Ten years later a second version of *The Scream*, as well as a *Madonna* also painted by Munch, was stolen from the Munch Museum on August 22, 2004, by masked gunmen. The City Government of Oslo offered a reward of 2 million kroner (approximately \$368,000) for the recovery of the painting, and, after a lengthy search, it was recovered on August 31, 2006. Of six original suspects, three were eventually convicted for the crime. Police disclosed no details surrounding the recovery operation, but both paintings are undergoing conservation for damage they suffered while out of the museum's care. Further to these restoration activities, the museum itself closed its doors for a period of 10 mo, during which time it underwent a \$5 million security overhaul, and upon reopening was dubbed by Norwegian journalists, "Fortress Munch."^[15]

A third example of a significant theft occurred at the Isabella Stewart Gardner Museum on March 18, 1990, and remains to this day the largest art theft committed in the United States in terms of value and number of works stolen. Disguised as Boston police officers, thieves entered the museum and stole 13 works by such distinguished artists as Johannes Vermeer, Rembrandt Harmenszoon van Rijn, Édouard Manet, and Edgar Degas along with French and Chinese artifacts. The significance of this crime lies not only in the number of works stolen, but also in their collective worth, which is estimated at upwards of \$500 million.^[16]

To this day the case remains unsolved. Due to the strict stipulations outlined in Isabella Gardner's will, the collection must remain on display permanently, forcing the museum to exhibit the empty frames of the stolen paintings in their original locations. A \$5 million reward for information or assistance in solving the crime has attracted numerous investigators and art theft institutions, however none have been able to successfully track down even one of the stolen works.^[17] Harold J. Smith, an iconic private art investigator, is immortalized in Rebecca Dreyfus' documentary of 2005, *Stolen*, which examines the theft at the Gardner and provides insight into the workings of art crime and the people and organizations that combat its continual spread. Until his death in 2005, Smith made cracking the Gardner theft his top priority.

Museum Responses to Theft

In the past, cases of theft have depended on the efforts of police officers and specialist art hunters, who have pursued museum objects as they would other types of stolen goods. In part, the search for these objects has been successful, because of the difficulties inherent in the disposal of well-known artifacts for criminals. It is challenging to sell recognized pieces on the open market unless a buyer is already arranged, since the fame of the object alone provokes a great deal of attention from members of the general public and the antiquities market, as well as legal authorities. For these reasons FBI Special Agent Robert Wittman noted that "the real art in art theft is not stealing, but selling."^[18]

There are a number of databases and search engines on the Internet today dedicated to tracking and locating stolen material. They allow for the systematic cataloging and access of stolen materials from around the world. The purpose of these types of research tools is to allow for the identification of stolen items before a purchase is made by an institution or individual, and also increase intelligence on illicit trade and sale. The Art Loss Register is the world's largest private online database of lost and stolen art, antiquities, and collectibles, listing approximately 170,000 items in 2006. It was created in London in 1991 as a result of the need for stakeholders in businesses, insurance companies, and associated art industries to minimize and deter art crimes, as well as facilitate the recovery of lost or stolen works.^[19] Many countries have created comparable databases; one American example is the National Stolen Art File used by the FBI Art Crime Team.^[20] Other organizations, such as the Association for Research into Crimes against Art (ARCA) and IFAR, have focused on the study of the motivations behind vandalism, theft, and even forgery, acting as consultants on protection and recovery issues.^[21,22] In addition to databases and think tanks, international police forces and investigation teams have made significant progress in deterring, recovering, and solving crimes by collaborating over a vast and complicated worldwide network of agencies. The three most established forces are those of the FBI Art Crime Team, the Metropolitan Police Art and Antiques Unit, and the Interpol Art Theft Division, which facilitate the sharing of information among different police departments.^[23–25]

Despite the sophistication of the international art tracking network, Julian Radcliffe, the Chairman of the Art Loss Register, has argued that art theft has remained a low priority for most of the world's police forces and governments.^[26] It is condemned by law throughout the world in the form of National Protective Laws on art and cultural property,^[27] and there is an increasing need for legitimate provenance, or history of the object, in the art and antiquities market; however few governments are willing to provide the funds or resources necessary to adequately hunt for lost art and artifacts. Italy is one of

the few countries to implement a strong political policy on this issue, including funding for specialized police forces that are equipped with hundreds of personnel, who specialize in crimes against cultural property.^[28] These groups include the Tutela Patrimonio Culturale, which protects Italy's cultural heritage, and the Nucleo Tutela Patrimonio Artistico, which specializes in the protection of artwork and in the recovery of stolen paintings.^[29]

Museums assist in counteracting weaknesses in art trade regulation and law enforcement by helping to publicize cases of theft in the media. The Art Gallery of Ontario issued news releases immediately following the theft of five ivory reliefs in 2004, which alerted the general public and art dealers to the crime, and made the pieces far more difficult to sell. The gallery also offered a \$120,000 Canadian reward for the return of the ivories, and a week after the theft, they were returned through an intermediary.^[30–32] The Isabella Stewart Gardner Museum has not yet recovered any of its stolen masterworks despite the \$5 million reward, but on the 15th anniversary of the theft, the museum issued a press release pleading for the proper maintenance of the works.^[33]

Unfortunately, some institutions have been tempted to minimize the situation in order to avoid negative publicity. One particularly dangerous and costly habit is the payment of ransom to thieves in return for stolen material. The Tate gallery in London, England, won back two J.M.W. Turner paintings that were stolen while on loan to the Schirn gallery in Frankfurt, Germany, in 1994 after paying over £6 million in ransom over many years. The J. Paul Getty Museum was also instrumental in the reclamation of Munch's *The Scream* in 1994 (mentioned earlier), on behalf of the Norwegian government.^[34] Responses like these may lead to the successful recovery of a prized artwork, but few organizations have the funds necessary for successful ransom payment, and there is concern that compliance with ransom demands may perpetuate the problem.

VANDALISM

Definitions of Vandalism

Unlike the more straightforward examples of theft, there is no singular, shared definition of vandalism within and among law, academia, and cultural heritage institutions. The disparity centers on questions of motivation and purpose, since “not all destruction is perceived as deliberate, but an event can be considered intentional or unintentional according to one's conception of nature or agency, and according to one's specific intentions in speaking of the damage.”^[35,36] Due to its sometimes ambiguous nature, few criminal codes even mention vandalism. The Criminal Code of Canada Section 430 refers to vandalism instead as “mischief” and describes it as willful destruction or damage of property that hinders the use, enjoyment, or

operation of the property for others.^[37] In the United States, the FBI Art Crime Team in Washington, DC, defines vandalism as an act with the intent “to willfully or maliciously destroy, injure, disfigure, or deface any public or private property, real or personal, without the consent of the owner or person having custody or control by cutting, tearing, breaking, marking, painting, drawing, covering with filth, or any other such means as may be specified by local law.”^[38] There are many other identified forms of vandalism, including burning, melting down, and decapitation, dismemberment, burying, and others.^[39] The tools vandals use to commit their crimes range from paint, lipstick, nail files, and gum to more violent devices, such as knives and acid.^[40]

Most of the academic definitions of vandalism come from the field of psychology. In *The Psychology of Vandalism*, Arnold P. Goldstein summarizes various definitions for vandalism and points out that they “collectively highlighted intentionality, destructiveness, and property ownership as the central features. . . of vandalism. . . [It] is an intentional act of destruction or defacement of property not one's own.”^[41] Many scholars have also proposed typologies and theories to explain vandalism and motivations for the act. Three theories in particular are most relevant to the discussion of vandalism in museums: Czikszenmihalyi and Larsen's “Enjoyment Theory,” which suggests that vandalism happens when intrinsic rewards from acts of destruction overpower the punitive effects of its consequences; Allen and Greenberger's “Aesthetic Theory,” which proposes that an interest in the appearance of an object after being vandalized could be an eliciting stimuli for vandalism; and Fisher and Baron's “Equity-Control Theory,” which offers that vandalistic behavior is a means to correct situations perceived to be wrong.^[42]

As art critic Michael Kimmelman noted, “it's tempting to look for a grand, unified theory of vandalism, but the specific motivations of the people who attack art are. . . as diverse as the objects they choose to hurt. More often it's not pranksters who slash art but self-promoters with a supposed cause.”^[43] It is, however, useful to have certain parameters to qualify cases of vandalism as art or crime, especially when debates between the two remain inconclusive and the boundaries between art and crime continue to blur.

A Brief History of Vandalism in Museums

The origin of the word vandalism comes from the Vandals, a Germanic tribe that invaded Western Europe in the fourth and fifth centuries A.D. Destroying Roman buildings and cultural artifacts, their actions were described as “barbaric ignorance, [with a] lack of taste and sensibility.”^[44,45] The association of their actions with art and culture ties the original meaning of “vandal” to the destruction and damage of cultural heritage. The term vandalism was officially coined in 1794, when

participants of the French Revolution destroyed art and monuments throughout the country,^[46] reinforcing the historic link between culture and the political acts of vandals.

Statistics show that public property is more often the target of vandalism than private property, due to the seemingly anonymous nature of both the owner of the object and the crime itself.^[47] Public sculptures are particularly vulnerable, pointed to by the theft and subsequent destruction of Henry Moore's *Reclining Figure* (created 1969–1970; vandalized 2006) from the Henry Moore Foundation in Hertfordshire, England, which was believed to have been melted down for the value of its bronze.^[48] In addition, the act of publicly assigning value to works of art and reinforcing perceptions of museums as “temples of fame” contribute publicity to the perceived benefits of vandalizing cultural heritage objects.^[49]

Some argue that destruction is an intrinsic aspect of culture as “the destruction of objects produces new meanings and practices, and damaged things may become more valuable than previous.”^[50] This phenomenon has even inspired new design aesthetics. The initial connection between vandalism and the accepted aesthetic is rooted in the Dada art movement with Marcel Duchamp and many other artists creating “non-art” in protest of society's bourgeois indulgence. Initially, the work focused on attacking imagery, such as Duchamp's work of art entitled *L.H.O.O. Q.* (1920), which involved vandalizing the cultural icon of the *Mona Lisa* with a drawn-on mustache and goatee applied to a reproduction of the famous painting.^[51] While the original work itself was not vandalized, Duchamp invoked its destruction by defacing the copy. Other inspired aesthetics progressed even further including “vandalizable sculpture” and auto-destructive art, developed by William Turnbull and Gustav Metzger, respectively, in the 1960s, as well as graffiti art made famous by Robert “Banksy” Banks, selling his works for over half a million dollars in the 1980s.^[52,53] Indeed, “the vandalism of the last century becomes today's tourist attraction” and institutions that argue against such forms of modern art may be interpreted as attacking “artistic innovation.”^[54,55] These forms of art that incorporate vandalism, as well as manifestations of performance art, challenge the status quo by forcing a duality of both condemning vandalism as a crime and inviting works of art rooted in vandalism into museum collections.

The historic role of the museum has also been in question regarding the acquisition, interpretation, and preservation of collections. When an artifact was removed from its original location, the link between the object and its ritual context changed, ultimately altering its appearance, value, and meaning, which were redefined through the representation and interpretation of that object in the institutional setting.^[56] In addition, material culture conservation sought to improve upon the past by altering its relics, revealing that “not even the most painstaking renovation conformed with original work.”^[57] The ethics of

conservation practice have since sought less intrusive treatments that are reversible. The reality that the work of conservators is not seen as vandalism illustrates the important role that societal perceptions and intentionality play in understanding vandalism within the museum context today.

Famous Cases of Vandalism in Museums

When Mary Richardson attacked Diego Rodríguez de Silva y Velázquez' *Rokeby Venus* on March 10, 1914, at the National Gallery in London,^[58] she demonstrated an instance in contemporary history of a case of vandalism that was clearly criminal. Richardson smashed the protective glass around the painting and cut the canvas seven times with a meat cleaver that she had concealed in her jacket.^[59] After attacking the painting, she was arrested at the museum. Despite her political motives to support the suffragette movement,^[59] Richardson's intentions in this case of ideological vandalism were to cause damage to the masterpiece. This political motivation drew attention to her specific cause through the destruction of cultural property.^[60] Richardson knew that she had no rights to, or ownership of, the painting, and she was aware that slashing the canvas would destroy it completely. In her statement to the Women's Social and Political Union she wrote, “I have tried to destroy the picture of the most beautiful woman in mythological history as a protest against the Government for destroying Mrs. Pankhurst, who is the most beautiful character in modern history.”^[58]

Vandalism also occurs when performance artists damage artifacts or works of art in order to make an artistic statement. In these cases of aesthetic vandalism, the artists' behaviors are no less vandalistic and illegal than the previous example, but the criminality is debatable in terms of artistic discourse, considering the underlying intention to create new art. On October 24, 1999, two art students, Yuan Chai and Jian Jun Xi, jumped onto Tracey Emin's work, *My Bed*, at the Tate gallery, and named the action *Two Naked Men Jump Into Tracey's Bed*.^[61] The pair was seminaked and staged a pillow fight on the bed, then attempted to drink from one of the vodka bottles on display.^[62] Security guards took them away before they could finish the rest of their performance plans, including touching the bed, smelling it, and performing “critical sex,” all of which they felt were necessary responses to the piece.^[61,62] Chai and Xi had slogans written on their bodies in English and Chinese that they claim were statements to “make the public think about what is good art.”^[61] They were detained at the police station, but ultimately were not charged, in accordance with the wishes of the artist and the museum.^[61,62]

As acts of vandalism are brought into public discourse, some forms, such as graffiti (mentioned earlier) eventually become recognized and legitimized as art. It was once seen as a form of “subversive public communication,”^[63]

but now is considered an art form from certain perspectives. In the process of creating graffiti, public property is defaced and therefore considered an illegal act of vandalism. However, the artistic quality of many graffiti paintings on buildings and moving subway cars attracted the attention of art collectors and entered the world of museums and art galleries in the form of large canvasses or pieces of paper in the late twentieth and early twenty-first centuries.^[63] For instance, from June 30 to September 3, 2006, the Brooklyn Museum presented an exhibition, titled *Graffiti*, which displayed 20 large-scale graffiti paintings from multiple artists.^[63] Such exhibitions blur the boundaries of graffiti's status as both a form of art and an accusable crime. Although the gallery graffiti pieces involved a change of medium from public property surfaces to canvasses or paper, the legitimization of graffiti as an art form extends from within the gallery or museum into the public sphere.

Museum Responses to Vandalism

Vandalism presents another serious threat to the ethical and professional responsibilities of museums and galleries. As with theft, the best responses are preventative measures that protect collections on display and prevent damage from occurring. Once vandalism has happened, museum responses are influenced by the severity of the damage and the value of the work that is affected.

The most passive response is no response, to the point where no legal action or claims for damages are made at all. This strategy might be explained by the belief that great publicity of a sensational crime only encourages the perpetrator and inspires other vandals, since ideological vandalism, for example, relies on publicity for the transmission of the message to a wider audience.^[64] The attack on the *Rokeby Venus* was impossible to hide in this manner, since the crime and political cause was so highly contentious. The gallery was closed temporarily, but women who attempted to visit it unaccompanied were denied admission for a longer period of time. More recently in 1999, Lars Kiel Bertelsen and Klaus Christensen were not permitted access to any archive files on the case in the National Gallery, London, and the writers argue that this refusal is symptomatic of the institutional repression of such acts of vandalism, even when the act itself was impossible to repress at the time.^[58]

While some museums have suppressed the effects of vandalism, others have attempted to harness the violence and chaos inherent in such acts in the name of creative expression. The Detroit Museum of New Art's (MONA) *kaBOOM!* program in 2002 is an example of a gallery show that encouraged visitors to participate in the creation and manipulation of art through its destruction. MONA announced that over the course of the exhibition, visitors would be invited "to smash, drop, throw, and slash artworks..." as an expression of the chaotic, violent

nature of modern life.^[65] The show was inspired by the work of the Dadaists, which rejected the traditional standards of aesthetics and intellectualism by embracing chaos, irrationality, and surrealism in literature, theater, and the visual arts. These artists also attempted to provoke violent visitor participation, as with the 1920 *Dada Spring Awakening* show, which included a large sculpture of the Dadaist, Max Ernst, with an axe beside it, along with an invitation to smash anything in the gallery.^[66] Both *kaBOOM!* and *Dada Spring Awakening* investigated the relationship between the artist and the visitor. Although the question remains as to whether permitted defacement can actually be defined as vandalism, by allowing visitors to demolish or alter works of art, these shows also transform the relationship that exists between the public and otherwise untouchable museum or gallery pieces. In this context vandalism is no longer a crime, but a positive, creative act that connects museums to their visitors.

An artifact or a work of art that has been vandalized requires some form of treatment to minimize the damage and prevent any further deterioration of the piece. Instances of smeared lipstick or smudged ink are relatively easy to treat while more serious cases, such as cuts in a canvas or cracks in a sculpture, require treatments that are more costly and time-consuming, and may even raise ethical issues for the museum because the restoration of an object automatically alters its original state. For example, Rembrandt's *Danae* (created 1636; vandalized 1985), which is held at the State Hermitage Museum in St. Petersburg, Russia, was slashed with a knife, and poured over with approximately 1 L of sulfuric acid. The attack occurred on a Saturday afternoon when the museum's director and members of the restoration department were off site. Since no immediate professional assistance was on hand, the damage to the painting was considerable. The first direct action taken to salvage the work was suggested by two professors from the St. Petersburg State Institute of Technology nearby, who arrived on the scene about an hour after the event and advised that the picture be kept upright and rinsed with water in order to minimize the destruction until the return of properly trained staff. Afterward, the work was painstakingly inspected by professional conservators, and over the next 12 years restorers at the Hermitage worked over the canvas with microscopes and specialized equipment, using a full-sized reproduction as a mapping guide. The process was extremely difficult, and the use of water has since been critiqued on the grounds that the extra liquid facilitated the spread of the acid, highlighting the many challenges museums face in responding to acts of vandalism.^[67]

PREVENTION OF THEFT AND VANDALISM IN MUSEUMS

As repositories for cultural property, museums have a public responsibility not only to respond to acts of theft

and vandalism appropriately, but also to protect the collections in their care. In 1974 ICOM established ICMS to publish a compilation of security recommendations, titled *Museum Security* (1977, 1993), for cultural heritage institutions worldwide. This was followed by the *Museum Security Survey* (1981), a companion book in the form of a detailed questionnaire designed to identify security risks in cultural facilities.^[68] Two principles that these books advocate are that every individual is responsible for the protection of cultural heritage, and that preventing crime in the museum means keeping the building secure 24 hr a day, every day of the year.^[69]

Security policies and procedures are an important aspect of museum protection. They allow staff to identify security goals and objectives, and to implement them in an institution-wide effort. Policies designate levels of responsibility and authority while setting out the existence of procedures, including key control, locks, access, property control, investigative services, security surveys, artifact escort, alarms, guards, exhibit security requirements, and storage security requirements. Both staff members and volunteers alike use procedures and regulations such as these when working in museums, which help to ensure a high standard of care for their respective collections.^[70]

From the building's exterior perimeter to the galleries' display cases, numerous low-tech measures are taken to prevent theft and vandalism in museums. Objects are separated, and thus protected, from visitors through the use of glass encasements, velvet ropes, metal bars, and raised platforms. To prevent theft, security hardware for cases and frames are used, such as specialized fasteners, screws, and hooks.^[70] To deter unwanted graffiti and some forms of play vandalism on art, ink- and scratch-resistant coatings are available for use on durable material types.^[71] To prevent damage, many museums establish rules of behavior for their galleries and require that large groups are chaperoned.^[72] Most institutions provide some form of a complimentary coat-check service so that visitors do not take bulky garments or oversized bags into the museum, because both of these could be used to smuggle tools into the galleries or sneak stolen objects out. Museums attempt to prevent theft and vandalism in the off-hours by locking all doors and windows and using exterior lighting as a deterrent for potential predators. Whenever possible, security systems ranging from alarms to on-duty security guards or regular police patrols are used to protect the museum and its collections.^[73]

In addition to these security measures, many museums are adopting a technological approach to protecting their objects within galleries and storage spaces, typically through alarms and surveillance. Equipment used to monitor a space includes closed-circuit television (CCTV) cameras as well as electromagnetic locks and key cards. CCTV cameras are installed in public spaces, while the image feeds to a central station, contacting security guards in the event of a suspicious incident. The systems may

range from elaborate color cameras with the ability to pan and tilt, to simpler cameras that provide black and white, static images.^[74]

Internal security is an extremely important measure for preventing theft and vandalism from occurring within gallery spaces. Limiting and tracking access to collections minimizes the risk of theft from storage areas. Few employees should have keys to a storage room, and in some cases, an identification check with a security guard is required prior to entry.^[75] Damage or theft can also occur when visitors gain access to these areas. A collections access policy is used to determine procedures, supervision, and levels of permission for visitors. Study areas, learning centers, visible storage, online catalogs, and photographs are all used to provide access to the collection without admittance to secure storage areas. Visitor screening is a common practice with permission given only to genuine researchers or students. In some cases, institutions require access request letters or forms, including institutional affiliation, purpose, duration of the study, proposed use of the information, and references. Vigilant record keeping discourages potential thieves and vandals as periodic inventories identify and potentially halt such acts.^[76]

Mechanisms to detect theft or vandalism can encompass an entire building or focus on a single artifact. Regardless of the area or object being protected, alarms consist of a sensor to identify a problem, a method of communicating and announcing the problem, and a response.^[74] There are a number of different types of sensors that are used to activate an alarm, including those triggered by vibration, motion, pressure, or disruption of an electric current. Exhibit cases carry such alarms, using sensors that activate when the glass is broken. Motion detectors are also useful in exhibits where artifacts or artworks are not contained within a case. If a visitor wanders too close, the alarm will chirp alerting both the individual and security personnel. Magnetic detectors are more suitable as general intrusion alarms around perimeter windows and exterior doors.

Traveling exhibitions and outgoing artifact loans are another security risk for museums. Formal loan agreements detail artifact inventories, conditions, insurance, and security procedures. A common practice is to use a designated courier whose responsibility it is to ensure the safety of the objects at all times.^[77] Transportation details are usually undisclosed, in the sense that travel routes, dates, and times are maintained on a need-to-know basis.^[78] Fine art transportation is a lucrative business worldwide with 79 independent firms belonging to the International Convention of Exhibition and Fine Art Transporters, where members meet annually to develop professional standards for the care and transport of art and antiquities.^[79]

Outdoor sites are more vulnerable to theft and vandalism because these spaces are not easily enclosed and are rarely guarded 24 hr a day. In many countries, laws exist

to deter theft by establishing such sites as protected and the artifacts as national property, prohibiting their collection, trade, or export. In 1970, in response to market demands for cultural property, the United Nations Educational, Scientific and Cultural Organization held the Convention on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Ownership of Cultural Property;^[80] it is ratified by 102 countries to date.^[81] In many countries, however, this does not eliminate cultural theft, since most artifacts from outdoor sites are not documented, and are either indiscoverable as protected objects or are inadequate evidence in court.^[82] The prevention of theft and vandalism to these types of public spaces is a continuing struggle facing professionals in the cultural heritage field today.

CONCLUSION

Accounts of theft and vandalism in museums and other public spaces highlights the value that society places on its collective heritage, and blurs the definitional lines between what is considered crime and what is considered art. In each instance, the motivations behind the action and the value of the art or artifact involved determine how the museum or public will respond to its loss or desecration. Theft presents a clear example of crime in museums, which may serve to increase both the monetary and emotional value of the object with its disappearance, as described in the case study of the theft of the *Mona Lisa*. While vandalism has traditionally been associated with some of the worst examples of museum crime, it has also acted as a powerful tool of self-expression and inspired art movements, pointed to by the discussion of the Dadaists and graffiti artists. The introduction of new technologies and systems in today's cultural heritage institutions allows for increased security and prevention against these and other criminal acts, as well as the shared knowledge and international effort toward the recovery of stolen goods. With these organizations and institutions working together, along with increased public awareness and societal responsibility, museums will ensure that all objects in their collections survive for the benefit of future generations.

KEY INDIVIDUALS AND ORGANIZATIONS

Art Loss Register: The world's largest private database of lost and stolen art, antiquities, and collectibles, created in London in 1991 to minimize and deter art crimes, as well as facilitate the recovery of lost or stolen works (<http://www.artloss.com>).

Association for Research into Crimes against Art (ARCA): Focuses on the motivations behind art vandalism and theft, as well as forgery, acting as consultants on art protection and recovery issues (<http://www.artcrime.info>).

Federal Bureau of Investigation Art Crime Team: The FBI established its Art Crime Team in 2004, composed of 12 Special Agents, each responsible for addressing art and cultural property crime cases in an assigned geographic region. The team is coordinated through the FBI's Art Theft Program in Washington, DC (<http://www.fbi.gov>).

International Convention of Exhibition and Fine Art Transporters (ICEFAT): A worldwide democratic organization of independent art transporters dedicated to promoting the highest standards of professionalism in the field of museum and gallery shipping (<http://www.icefat.org>).

International Council of Museums (ICOM): An international network of museum professionals, institutions, and committees held to their own Code of Ethics in museums (<http://icom.museum>).

International Committee on Museum Security (ICOM-ICMS): A committee formed by ICOM to represent and support their aims and objectives with reference to museum security by providing advice, programs, and forums for museum professionals.

International Foundation for Art Research (IFAR): This organization offers information on authenticity, ownership, theft, and legal and ethical issues related to stolen objects, including issues of looting followed by repatriation, and scholarly information related to ownership and law (<http://www.ifar.org>).

Interpol Art Theft Division: A division of the U.K. police force, which facilitates the sharing of information related to the theft and disappearance of art and artifacts among different police departments in the effort of recovery (<http://www.interpol.int>).

Metropolitan Police Art and Antiques Unit: This unit is responsible for the collation and dissemination of intelligence pertaining to art crime and continues to run and update the London Stolen Art Database (<http://www.met.police.uk/artandantiques/>).

Museum Security Network (MSN): This organization provides a listserv for museum professionals, providing current events related to security and crime in cultural heritage institutions (<http://www.museum-security.org>).

National Stolen Art File: An American register used by the FBI Art Crime Team to minimize and deter art crimes, as well as facilitate the recovery of lost or stolen works (<http://www.fbi.gov>).

United Nations Educational, Scientific and Cultural Organization (UNESCO): A United Nations agency that promotes international cooperation in the fields of education, science, culture, and communication (<http://www.unesco.org>).

ACKNOWLEDGMENTS

Theological Librarianship

Paul F. Stuehrenberg

Yale Divinity Library, New Haven, Connecticut, U.S.A.

Abstract

Christian theological libraries trace their origins to the early church. Early centers included Jerusalem, Alexandria, and, most famously, Caesarea, where the library supported the work of such scholars as Origen, Eusebius, and Jerome. The Vivarium, a religious community founded by Cassiodorus, provided a model for medieval monastic libraries. At the close of the Middle Ages faculties of theology developed libraries that continue to this day. In North America independent seminaries and schools of theology appeared in the early nineteenth century in response to the rise of Unitarianism. The American Theological Library Association was founded in 1947 in part to improve standards for theological libraries. It has played a leadership role in the professional development of theological librarians, and the indexing and preservation of theological literature. Theological libraries range in size from small operations supporting the curriculum to comprehensive research institutions. Many theological libraries remain small and underfunded.

When you come, bring the cloak I left with Carpus at Troas, also the books, and above all the parchments (2 Tim.4:13).

Theology is a text-based discipline. From their beginnings, Christians used books. For Christian theology those texts begin with the Bible, originally the Hebrew Bible, or Old Testament, and its Greek translation, the Septuagint. Then, early in its history, Christians adopted selected apostolic writings as the New Testament. There were also other, noncanonical writings, both Christian and Jewish, almost from the beginning, some of which no longer survive. Other early Christian literature includes sermons, letters, and, increasingly as time went by, polemical and apologetic treatises. The growth of the literature of theology led to the creation of libraries.

ORIGINS

There were three types of early Christian libraries: congregational, larger libraries in Christian centers, and monastic. Even small communities built libraries that served their liturgical, catechetical, and archival needs. The libraries established at larger centers helped to support scholarship, often with the support of the local bishop.^[1] Early centers included Jerusalem, Alexandria, and, most famously, Caesarea.

The library at Caesarea is a model for how Christian libraries were created and how they were supported during the first centuries after Christ. Origen (ca. 185-ca. 254) moved from Alexandria to Caesarea, bringing with him his personal library, which included Biblical texts,

commentaries, and technical works. Origen used his library as the basis for a prolific output of commentaries, homilies, and other works of scholarship. His most notable work was the Hexapla, which included the Hebrew and Greek texts of the Old Testament in parallel columns. Late in the third century, a wealthy Christian presbyter, Pamphilus (d. 310), settled in Caesarea and began to accumulate a library of sacred works, the core of which came from Origen's library. The collection that he built became so famous in latter antiquity that it was described, with some exaggeration, as the Christian equivalent of the library of Alexandria. Like the library of Alexandria, this was no mere collection of books, but a place where books were copied, emended, and produced. Eusebius (260–339), Pamphilus' student and the eventual bishop of the city, continued to expand the library and based his scholarship upon it. Jerome notes that Euzoios, bishop of Caesarea from ca. 376 to ca. 379, set out to restore the library by having its holdings copied from papyrus scrolls onto parchment codices.^[2]

Christians were early adopters of the codex. By the end of the first century the codex became the standard format used by Christians, while others in the ancient world continued to use the papyrus scroll. The advantages of the codex include economy (writing on both sides of paper), compactness, comprehensiveness (collected editions), convenience of use (it can be read using one hand rather than two), and ease of reference.^[3]

One of the best documented monastic libraries was that founded by Cassiodorus (ca. 487–ca. 580). After a distinguished political career, Cassiodorus founded a monastic community called the Vivarium. Here he brought together a large library of Christian and classical texts for the

education of the community of monks, as described in his *Institutiones divinarum et saecularium litterarum*. The community was not only to study the books he gathered, but was also charged with producing copies.^[4] The Vivarium came to serve as a model that was followed by monastic communities during the Middle Ages. Indeed, it is due in no small part to these monastic communities that the literature of antiquity, both Christian and secular, survived. An example of the use to which such a library could be made is provided by the Venerable Bede (673–735), who, working independently, but with access to a good library at the monastery at Jarrow, produced impressive works of scholarship that were highly valued throughout the Middle Ages. The library upon which he relied was destroyed by Viking raiders in about 860.

EUROPEAN THEOLOGICAL LIBRARIES

Effective as they were at preserving the literature of antiquity, monasteries were not learned academies, but rather, “schools for the practice of virtue.”^[5] While Roman civilization remained alive in isolated communities, there was a general decline in learning after the fall of the Roman Empire. This was arrested for a time by the Carolingians, who aimed for nothing less than the reform of society through education, especially in the language arts, with the goal of establishing a Christian civilization. Their essential contribution was that they established a minimal standard of literacy to be promoted “by every bishop and every abbot,” and that the enterprise was to be underwritten by the consistent and generous patronage of the state.^[6] The result was a sustained period of creativity. Scholars emended ancient texts and wrote new works designed to undergird the study of the liberal arts and sacred texts. Teams of scribes toiled in scriptoria to produce manuscripts both for their own use and for distribution.^[7] Indeed, very little literature survives from the ancient world, sacred or profane, that was not copied during the Carolingian era. To train the scribes, religious leaders, and government officials necessary to support their empire and its programs, the Carolingians established schools that were supported by the public authority. Associated with the better schools were libraries. Laon stands as one example of the cathedral library.^[8]

By the twelfth century the cathedral and monastic schools began to give way to a new way of studying of theology. Up to this point scholars had worked largely independently, despite the advances made under the Carolingians. In the twelfth century for the first time there was a large enough community of teaching masters and an environment in which they and their pupils could meet freely for it to be possible to speak of a general revision of educational methods and purposes.^[9] In this context the study of theology as an academic discipline evolved. Bernard of Chartres described himself and his twelfth-century

contemporaries as “dwarfs standing on the shoulders of giants.”^[10] The masters of the twelfth-century were not, for the most part, great men, but the schools they set up were for the first time recognizably “academic” in the modern sense, in that they were characterized by a steady aggregation of small changes. The schools that grew up in the twelfth century prepared the way for the development of the university in the thirteenth. The books that were to become the basic theological textbooks for the remainder of the Middle Ages were written during the twelfth century, including the *Glossa ordinaria*, a compilation of patristic commentary on the Biblical text, the *Historia scholastica* of Peter Comestor, an aid for understanding the literal sense of the Bible, and, most important, the *Sentences* of Peter Lombard, which might be characterized as the first systematic theology textbook. These textbooks were a new kind of book—not meant to be read straight through, but rather to serve as references, complete with such apparatuses as indexes, running heads, and marginal notations.^[11]

The educational model that developed was for basic education to take place in the grammar school, then the study of the seven liberal arts in an academy or Latin school, followed by the study of theology in a university faculty of theology.^[12] As the schools developed, they gathered libraries to support their teaching. The pattern remained much the same following the Reformation, with the exception that the faculties of theology would be either Protestant or Roman Catholic.

THE NORTH AMERICAN EXPERIENCE

From colonial times Protestants in North America adopted the English model for training clergy. Colleges were established for the training of leaders for “church and civil state,” in the words of Yale’s charter. For most clergy in colonial times the bachelor’s degree provided sufficient training. A minority might choose to read theology with a college professor or with a local clergyman. This practice increased somewhat after the Great Awakening, so much so that some senior clergy became what might be called “one-teacher schools,” with several students in residence at any given time.^[13] The rise of Unitarianism in the beginning of the nineteenth century led to the perceived need to have better trained clergy, which led to the creation of theological seminaries, beginning with Andover in 1808. Within the next two decades the number of theological seminaries and divinity schools mushroomed. Many of the smaller seminaries were “poorly endowed, inadequately staffed and under-enrolled.” There are three indicators of the relative strength of the schools: the size of faculty, the number of students enrolled, and the size of library. “Although the number of books in the library was not an absolute guide to the quality of education, a rough correlation existed between library acquisitions and

educational standards,” for the availability of an adequate library was the major factor supporting the professional development of faculty.^[14]

Standards for theological seminaries remained problematic throughout the nineteenth century and into the twentieth. The Conference of Theological Schools was created in 1920 to help the schools address this problem. This organization was restructured in 1936 as an accrediting agency, the American Association of Theological Schools (AATS). Of the 46 schools accredited in its first year, all but 11 had notations for lack of adherence to standards. One initiative the AATS (later, ATS) undertook to improve the libraries of its member institutions was to help to found the American Theological Library Association (ATLA) in 1947. Yet, even though each successive version of the AATS standards would raise the bar for seminary libraries, especially for professional staff, many seminary libraries have remained small and poorly financed.^[15]

THE ATLA

The first meeting of what was to become the ATLA took place June 23–24, 1947, at Louisville Presbyterian Seminary. For a fuller account of the first 50 years of the American Theological Library Association, see O’Brien and O’Brien.^[16] AATS invited 110 institutions to the meeting. Fifty librarians, one seminary president, and one dean attended. From the outset they faced daunting problems, and set about immediately to address them. At the very first conference a committee was appointed to look into the indexing of theological journals. By 1952 the committee had devised a plan whereby staff at 20 institutions would share responsibility for indexing, under the leadership of Stillson Judah. The result was the *Index to religious periodical literature*. The 1949 conference appointed a Committee on Microphotography. Initially the purpose of its program was to reproduce the literature of theology so that the texts could be distributed to member institutions. In 1951 a committee on cataloging and classification was appointed. One of the problems they faced was that theological libraries at the time were using at least three different classification systems: the Dewey Decimal System, the Library of Congress classification system, and the system devised by Julia Pettee at Union Theological Seminary in New York. For more on her remarkable career, see Spoor.^[17] In 1952 there was a joint ATLA/AATS committee on accreditation standards. The new standards shifted the emphasis on adequacy away from quantitative measurement to a focus on the educational process.

The importance of ATLA’s efforts was recognized within a decade of its founding by the awarding of several grants. In 1956 the Sealantic Fund gave ATLA a grant of \$110,000: \$80,000 for microtext and \$30,000 for

indexing. To oversee the expenditure of these funds, the following year the Board of Microtext was organized, with Raymond P. Morris as chair (he served until his retirement in 1972). That same year the Board on Religious Periodical Literature was established with Jannette E. Newhall as chair and Lucy Markley as editor. In 1960 Calvin Schmitt was appointed chair (he retired in 1979) and G. Fay Dickerson as indexer (she retired in 1984). The experiment of having volunteers prepare the index came to an end.

In the 1960s ATLA received a series of grants from the Lilly Endowment and the Sealantic Fund for the training of theological librarians. The normal pattern up to that time was that schools would appoint a faculty member as the librarian, who would oversee a staff with training in library science, but no background in theology. The programs developed with this funding were sufficiently successful that a decade later the norm became that library staff would have training in both library science and theology.

Another transformative grant was received in 1961: the Sealantic Fund gave \$875,000 to support the Library Development Program. The primary objective of the Program was to increase book purchases, thereby strengthening the libraries’ collections. The Program was designed in such a way that participating libraries would also have to increase staffing levels to participate. By the third year of the grant, all 85 eligible AATS institutions participated in the Program either fully or in part. Library expenditures rose in those three years from \$2.8 million to more than \$3.877 million. For more on the Library Development Program, see Stuehrenberg.^[18]

By the 1970s there was a growing recognition of the need for preservation of microfilming. Charles Willard and Andrew Scrimgeour conducted a study that led to the creation for preservation microfilming program for monographs. In September 1985 Robert P. Markham was hired as the Director of Programs for the preservation effort. ATLA became a significant participant in national efforts to reformat brittle books. Over the period of 1987–1992, ATLA received nine National Endowment for the Humanities (NEH) grants totaling \$1,524,330 and filmed 19,000 titles. ATLA continued an active preservation program into the new millennium. Recent microfilming projects receiving NEH funding include Christianity and the Encounter with World Religions, 1850–1950, African American Religious Serials, 1850–1950, and Religious Periodical Literature of the Hispanic and Indigenous People of the Americas, 1850–1985.

In 1976 the *Index to religious periodical literature* was renamed *Religion index one*, and ATLA began the publication of *Religion index two: multiauthor works*. This was followed in 1980 by a volume indexing *Festschriften, 1960–1969*, which was prepared by Betty and Elmer O’Brien. In 1982 a retrospective project, *Religion index two: multiauthor works, 1970–1975*, filled in the gaps

between the two publications. The last print volume of *Religion index two* appeared in 1999.

The *ATLA religion database*, incorporating both *Religion index one* (periodicals) and *Religion index two* (multiauthor works) first appeared on CD-Rom in 1989. Initially it was published and distributed by H.W. Wilson. That arrangement ceased in February 1993, when ATLA first produced its own disc. For an account of the birth of the ATLA religion database on CD-Rom, see Moore.^[19] In 2008 ATLA discontinued all CD-Rom products, with the database now available online.

The *Ethics index* was conceived of as a way for ATLA to broaden its presence in the electronic reference marketplace and to serve as a source of additional revenues during a period of institutional downsizing and scarcity of funds among theological libraries. It first appeared in February 1994. However, the anticipated expanded market did not materialize, and the ATLA budget was in deficit for two years in a row. ATLA abandoned the project, with the last CD-Rom appearing in June 1996. ATLA was forced to reduce staff in order not to go bankrupt, and then began rebuilding.

In 1997 ATLA signed contracts with SilverPlatter and FirstSearch to distribute the *ATLA religion database*, followed in 1999 with Ebsco. These agreements paved the way for a dramatic increase in ATLA's revenues, a phenomenon that has continued to this day. The *ATLA religion database* is now accepted as the standard index for religious periodical literature in the academic marketplace.

In 2001 ATLA undertook the Retrospective Indexing Project, which consisted of the indexing of pre-1949 volumes of titles included in the *Index to religious periodical literature*. More than 100 institutional members pledged support. Originally 134 titles were on the list for retrospective indexing. The project ended in August 2005 with 40,000 index records for 47 periodical titles.

In 1999 ATLA announced the coming of ATLAS (ATLA serials), with a promise to supply full-text electronic access to 50 years of 50 journals. The project was launched on January 31, 2001, with a \$3.94 million grant from the Lilly Endowment. As of August 2006 there were 86 journal titles in ATLAS and 192,768 articles.

Also in 1999 ATLA completed the conversion of the back file of *Old Testament abstracts* and signed an agreement to produce an electronic edition of *Catholic periodical and literature index*. In 2004 *New Testament abstracts* was added to its electronic publications.

From 1985 to 1991 ATLA underwent a thorough restructuring of its governance, programs, finances, and staffing. The restructuring followed a financial management study by Peat, Marwick funded by a \$25,000 Lilly Endowment grant. Previously ATLA's management structure was thoroughly decentralized, with operations dispersed between such places as Chicago, Princeton, and St. Meinrad, with bank accounts in Fort Worth,

incorporation in Delaware, and executive responsibility changing location each year to wherever the president might be located. The reorganization merged ATLA's two semiautonomous program boards (Preservation and Indexing) with the Board of Directors, resulting in one Board with the power to define the association's mission and to set policy. By appointing an executive director as the chief executive officer, bringing all staff together at a headquarters location, adopting a unified budget, and following accepted accounting procedures, ATLA was able to use its resources more effectively.^[20]

In the reorganization, ATLA adopted the Carver Policy Governance model (<http://www.carvergovernance.com/model.htm>), under which the Board of Directors sets policies and charges the Executive Director with carrying them out within certain executive limitations. The mission of ATLA is currently defined as fostering the study of theology and religion by enhancing the development of theological and religious libraries and librarianship. In pursuit of that mission ATLA (<http://www.atla.com/about/html>) has four organizational ends:

1. To foster the professional growth of its members, and to enhance their ability to serve their constituencies as administrators and librarians.
2. To advance the profession of theological librarianship, and to assist theological librarians in defining and interpreting the proper role and function of libraries in theological education.
3. To promote quality library and information services in support of teaching, learning, and research in theology, religion, and related disciplines, and to create such tools and aids as may be helpful in accomplishing this.
4. To stimulate purposeful collaboration among librarians of theological libraries and religious studies collections; and to develop programmatic solutions to information-related problems common to those librarians and collections.

The membership elects the Board of Directors, who have "moral ownership" of the Association. The structure of the annual conference was changed from having standing committees to the establishment of "Interest Groups," which are created by the membership. The current interest groups include Collection Evaluation and Development, College and University, Judaica, Lesbian and Gay, Public Services, Special Collections, Technical Services, World Christianity, and World Religions. Denominational groups also meet at the annual conference.

Since the Executive Director is responsible for carrying out policies established by the Board of Directors, the Executive Director appoints advisory committees that help the Executive Director to understand the interests of the membership. Current advisory committees include the Professional Development Committee and the

Publications Committee. The Executive Director also appoints the Annual Conference Committee and the Education Committee, which is responsible for continuing education at the annual conference. Standing committees of the Board of Directors include the Endowment Committee and the Nominating Committee. The Special Committee of the Association for International Collaboration coordinates the Association's activities regarding international theological librarianship, supports efforts of individual libraries and librarians to participate in international theological librarianship activities, and plans annual conference activities relating to international theological librarianship.

Before the reorganization members volunteered hundreds of hours each year to running the projects, programs, boards, and committees of the Association. With the reorganization members now rely on professional staff to manage the Association's affairs, leaving the members free to focus on furthering the professional ends of theological librarianship.

Begun as an association of Protestant theological libraries from North America, ATLA now is the premier professional association for theological libraries for all branches of Christianity, Protestant, Roman Catholic, and Eastern Orthodox. While member libraries are still primarily from North America, ATLA has a growing number of international library institutional and individual members, as well. Individual and institutional members are listed in the annual *Summary of Proceedings*.

OTHER PROFESSIONAL ASSOCIATIONS SUPPORTING THE WORK OF THEOLOGICAL LIBRARIES

The Association of Christian Librarians (<http://www.acl.org/>) was established in 1957, and today has more than 500 individual and nearly 150 institutional members representing a wide spectrum of denominations. Members work in a variety of libraries, including Bible colleges, seminaries, colleges, and universities. Members are asked to subscribe to a statement of faith. They publish the periodical the *Christian librarian*, and print and online versions of the *Christian periodical index*, the leading guide to periodical literature from the evangelical perspective.

The Association of Jewish Libraries (AJL) (<http://www.jewishlibraries.org/ajlweb/index.htm>) promotes Jewish literacy through enhancement of libraries and library resources and through leadership for the profession and practitioners of Judaica librarianship. AJL was created in 1965 as a result of the merger of two organizations: the Jewish Librarians Association (founded in 1946), which concerned itself with collections of Judaica in academic, archival, or research institutions and the Jewish Library Association (founded in 1962), which concerned itself

with collections in synagogue, school, and community center libraries, as well as other smaller libraries and media centers. They publish a quarterly newsletter, convention proceedings, and an annual scholarly publication, *Judaica librarianship*.

Established in 1921, the Catholic Library Association (CLA) (<http://www.cathla.org/index.php>) is an international membership organization, providing its members professional development through educational and networking experiences, publications, scholarships, and other services. CLA coordinates the exchange of ideas, provides a source of inspirational support and guidance in ethical issues related to librarianship, and offers fellowship for those who seek, serve, preserve, and share the word in all its forms. Members come from a variety of institutions, from primary schools and congregational libraries to universities and seminaries. CLA publishes a quarterly journal, the *Catholic library world*, and the *Catholic periodical and literature index* (now distributed in electronic form in partnership with ATLA).

INTERNATIONAL THEOLOGICAL LIBRARY ASSOCIATIONS

Australian and New Zealand Theological Library Association (ANZTLA) (<http://www.anztla.org/>), founded in 1985, is an association of both individual and institutional members. It maintains the *Australasian religion index online* (formerly published as a print index since 1989) and the *Australasian union list of serials in theological collections online* and an online *Newsletter*.

The Forum of Asian Theological Librarians (ForATL) (<http://www.foratl.org/index.htm>) traces its origins to the Consultation of Asian Theological Librarians held in May 1991 in Chiang Mai, Thailand, under the sponsorship of the Programme for Theology and Cultures in Asia. It has institutional and individual members from throughout Asia. Membership is chiefly from Protestant institutions. It sponsors periodic consultations and has published a directory of Asian theological libraries.

Bibliothèques Européennes de Théologie (BETH) (<http://www.theo.kuleuven.be/beth/>) was founded in 1954 under the auspices of UNESCO as the International Association of Theological Libraries. Today BETH is an ecumenical association of the national theological library associations in Europe, with additional members gathered from among the various individual theological libraries that are recognized as extraordinary in their scope, either from their collections or from their influence in the international sphere. For an account of the founding of BETH, see Geuns and Wolf-Dahm.^[21]

Red Latinoamericana de Información (RLIT; formerly the Latin American Theological Information Network, <http://www.ibiblio.org/rlit/>) was founded in 1994 and has members from throughout Central and South America. It

is open to all theological libraries, but membership is predominantly Protestant.

In addition, there are national theological library associations in many countries.

THEOLOGICAL LIBRARIES TODAY

Theological libraries today are a diverse group of institutions, ranging from one-person operations to denominational seminary libraries to university-related divinity libraries. Theological libraries can be divided into four categories. The first two types have collections that essentially support the curriculum in the broader sense; that is, besides the curriculum proper, they provide access to the Christian heritage reflected in the curriculum. The first type collects materials almost exclusively North American publications, with only a minimum of foreign materials. This type of library likely acquires between 800 and 1200 volumes per year and not more than 200–300 journals. Type two libraries would acquire additional foreign materials and their acquisitions programs might double that of type one libraries. A type three library also gathers documentary literature, understood as a broad segment of non-scholarly religious literature, such as the literature produced by a denomination. Type four libraries are research institutions. They seek to acquire the scholarly literature essential to the history and development of all branches of Christian thought without regard to language, date, country of origin, and theological perspective. The focus is not on being exhaustive, but on acquiring the scholarly literature that has defined and is shaping Christian thought.^[22]

In the 1970s ATS encouraged theological schools to merge their libraries to make it possible to build larger, more efficient libraries. The Graduate Theological Union in Berkeley, CA, is one of the more successful examples. Nine schools went together to create what instantly became one of the largest theological libraries in the country. Their cooperation also enabled them to create a graduate program that none of them could have accomplished on their own. Another example is the JKM Library in Chicago, which now serves the Lutheran School of Theology at Chicago and McCormick Theological Seminary. Both institutions, while maintaining their separate identity, are now located in the same complex with a common library. The three seminaries of the Eastern Cluster of Lutheran Seminaries (located in Columbia, SC; Gettysburg; and Philadelphia, PA) have undertaken the experiment of having one library in three locations, with a common collection development policy. Books remain in the physical location where they last circulated. Many other seminaries have developed distance education sites, or satellite campuses, requiring them to find creative ways of providing library services.

The world of theological librarianship is relatively small. In 2005 ATLA had 492 individual members and

265 institutional members. That means that there are relatively few positions open at any given time. But when a position does come open, qualified candidates are highly sought after. Theological libraries in North America today tend to prefer candidates for professional positions who have at least masters' degrees in both library science and theology (or a related discipline). For training in library science, most candidates follow the academic librarianship track in ALA-accredited schools. ATLA now sponsors a course in theological librarianship offered through the University of Illinois that can be taken by students at other institutions as a part of their program. Postings for some directorships require a doctorate, usually in one of the disciplines of theology. Many institutions outside of North America tend to require less theological training for library staff, often assigning some professional activity, such as book selection, to faculty.

In a recent survey two-thirds of the theological librarians responding considered theological librarianship to be a ministry, while the other third considered themselves to be in an occupation that happened to be at a theological institution.^[23] Many theological librarians, especially those in denominational seminary libraries, may also be ordained clergy. Many theological librarians have faculty status, especially for the director, sometimes for other professional staff as well. Theologically trained librarians also work in other types of libraries, as well, especially college and university libraries, doing a variety of tasks, such as subject bibliographers, general reference, and cataloging of humanities resources.

As is the case with librarianship in general, technology is changing theological librarianship. While an increasing number of theological journals are available electronically, many are still available only in print, and likely will be for some time. In part this is because most religion periodicals are published by organizations that issue one or two journals. As already noted, ATLA is one of the major providers of electronic periodicals through ATLAS. On the other hand, since theology is a text-based discipline, there is an increasing corpus of theological texts available electronically. Several publishers provide packages of Biblical texts and reference works, including Logos Bible Software and BibleWorks. Patristic and medieval authors are covered by the electronic editions of *Patrologia Latina*, *Patrologia Graeca*, and *Corpus Christianorum*. *Past Masters* provides critical texts for selected philosophers and theologians. And there are electronic texts available for an increasing number of theologians, including such figures as Thomas Aquinas, Martin Luther, and Karl Barth.

What of the future of theological libraries? According to Dan Aleshire, Executive Director of ATS, they will be with us for the foreseeable future. The purpose of the academic library has been to provide access to trustworthy, authoritative knowledge. The library has historically controlled for "authoritative and trustworthy" through its

collection development policies, and controlled for "access" through its organizing, cataloging, and circulating.^[24] While the manner in which libraries deliver those services in the future may vary, teaching and research will continue to have need of those services.

Topic Maps

Steve Pepper

Department of Linguistics, University of Oslo, Oslo, Norway

Abstract

Topic Maps is an international standard technology for describing knowledge structures and using them to improve the findability of information. It is based on a formal model that subsumes those of traditional finding aids such as indexes, glossaries, and thesauri, and extends them to cater for the additional complexities of digital information. Topic Maps is increasingly used in enterprise information integration, knowledge management, e-learning, and digital libraries, and as the foundation for Web-based information delivery solutions. This entry provides a comprehensive treatment of the core concepts, as well as describing the background and current status of the standard and its relationship to traditional knowledge organization techniques.

INTRODUCTION

Topic Maps is a standard technology for describing knowledge structures and using them to improve the findability of information. It is based on a formal model that subsumes those of traditional finding aids, such as indexes, glossaries, and thesauri, and caters for the additional complexities of digital information. The model is defined in an ISO standard (ISO 13250), along with interchange syntaxes, a formal semantics, and a graphical notation. Ancillary standards define a Topic Maps Query Language (TMQL), a Topic Maps Constraint Language (TMCL), and mappings to other knowledge organization specifications, such as Dublin Core. Since its initial standardization in 2000, Topic Maps is finding increasing application as the foundation for Web sites and portals, as well as in knowledge management (KM), e-learning, and more.

This entry provides a comprehensive treatment of the core concepts, in addition to the background and current status of the standard, its relationship to traditional knowledge organization techniques, and examples of the kinds of applications for which it is being used. This entry follows the established convention of using initial capitals (“Topic Maps”) when referring to the standard itself or the technology in general, and lower case (“topic maps”) when referring to the document-like artifacts created through the application of that technology.

BACKGROUND AND HISTORY

Origin and Development

The concepts of Topic Maps originated in the context of the Davenport Group, during the development of the DocBook application, as an answer to the problem of how to automate the merging of (digital) back-of-book

indexes. The key insight, due to Dr. Steven R. Newcomb, was that such indexes are in fact models of knowledge. Their digital encoding is based on their surface appearance, but they actually have an implicit, underlying structure. If that structure could be represented formally, it would be possible to automate the merging process.

An initial model was defined in 1992 using the concepts of the HyTime standard, of which Dr. Newcomb was coeditor, under the auspices of a project called the Conventions for the Application of HyTime (CApH), sponsored by the Graphics Communications Association Research Institute (GCARI). After a number of iterations, during which the model was gradually refined, the work was brought into ISO, and went through further revision cycles before being adopted as ISO 13250:2000 under the editorship of Newcomb and coeditors Dr. Michel Biezunski and Martin Bryan. Responsibility was given to Working Group 3 of the subcommittee ISO/IEC JTC 1/SC 34.

The standard was originally defined in terms of an SGML DTD. In fact, it was defined in terms of a “meta-DTD” according to the SGML Architecture facility offered by the draft HyTime standard. Although never finally standardized, the concepts inherent in meta-DTDs found their way into DITA, XML namespaces, and HTML “microformats.” By the time it was published, Extensible Markup Language (XML) was replacing SGML, especially on the Web. In order to create an XML-based version of the specification an ad hoc working group called TopicMaps.Org was formed by Newcomb and Biezunski and this resulted in the publication in March 2001 of *XML Topic Maps (XTM) 1.0*,^[1] edited by Steve Pepper and Graham Moore.

In addition to defining a new, XML-compatible DTD for representing topic maps, the new specification removed the dependence on HyTime, clarified some of the terminology, and simplified parts of the model. XTM gained immediate recognition and has to all intents and

purposes replaced the original version. In 2003, the XTM DTD was folded back into the second edition of the ISO standard^[2] and from that point on stewardship of the standard passed back to the ISO committee.

Current Status

In 2003 a road map was devised for the further development of the standard, to include a data model, reference model, query language, and constraint language. As of the present writing (late 2008), the Topic Maps family of ISO specifications is as follows:

- ISO/IEC 13250: Information Technology—Topic Maps—
 - Part 1: Overview and basic concepts^[3]
 - Part 2: Data model^[4]
 - Part 3: XML syntax^[5]
 - Part 4: Canonicalization^[6]
 - Part 5: Reference model^[7]
 - Part 6: Compact syntax^[8]
 - Part 7: Graphical notation^[9]
- ISO/IEC 18048: Information Technology—TQML^[10]
- ISO/IEC 19076: Information Technology—TMCL^[11]
- ISO/IEC TR 29111: Information Technology—Topic Maps—Expressing Dublin Core Metadata using Topic Maps^[12]

Parts 2 and 3 were published in 2007. Most of the remainder exist as stable drafts and are expected to be published in 2009. Work continues in SC 34/WG 3 and interested parties are encouraged to attend meetings and participate through their national standards bodies. For further information, see the SC 34 Web site at <http://www.jtc1sc34.org> and the WG 3 Web site at <http://www.isotopicmaps.org>.

CORE CONCEPTS

This section presents the core concepts of the Topic Maps paradigm. The back-of-book index is used throughout as a familiar point of reference for illustrative purposes. In line with long-established tradition in the Topic Maps community, this entry will use the domain of opera for its examples, based on the *Italian Opera Topic Map*.^[13]

Subjects

The core concepts of Topic Maps are relatively few and for the most part easily grasped. They are often referred to as the “TAO of Topic Maps,” after the eponymous paper which has served as a basic introduction since it was first published in 2000.^[14] However, even more fundamental than the TAO is the emphasis on *subjects*.

In the Topic Maps world view, the most essential property of information is not where it resides (the document-

centric view) or which application was used to create it (the application-centric view), but its *aboutness*, i.e., the subject (or subjects) that it is about. This subject-centric view lies at the very heart of the Topic Maps paradigm.

There are many reasons for insisting on the primacy of subjects: the starting point for most acts of information retrieval (e.g., searches on the Web) is one or more subjects; in the aggregation of information and knowledge, subjects usually constitute the most useful collation points; in fact, the whole purpose of creating information can be viewed as capturing knowledge *about certain subjects* in order that it can be shared and reused. While other forms of metadata such as author, publisher, and creation date are important for certain information management tasks, for the key end-user task of information retrieval, aboutness is most critical. Since the purpose of Topic Maps is to alleviate infoglut and improve the findability of information, subject-centricity is the central feature.

Subjects and topics

The concept of “subject” is defined by ISO/IEC 13250:2006^[4] as follows:

3.14 subject

anything whatsoever, regardless of whether it exists or has any other specific characteristics, about which anything whatsoever may be asserted by any means whatsoever

A subject, in other words, is literally anything about which the author of a topic map wishes to make assertions. Typical subjects in the domain of opera might be the composer Giacomo Puccini; his operas, including *Tosca* and *Madama Butterfly*; Lucca, the city where Puccini was born; and Teatro Costanzi, where *Tosca* was first performed. These are also the kind of subjects one would expect to find in the index of a book on opera.

The Topic Maps data model (TMDM)^[4] defines a model for representing subjects such as these, and assertions about them, within an information system. The Topic Maps Reference Model (TMRM),^[7] which offers a more abstract and low-level model, is described below. In order to represent a subject a proxy is required, and this is called a “topic.” A topic is thus the (symbolic) representation of a (nonsymbolic) referent, i.e., the subject. In the words of the standard:

3.18 topic

symbol used within a topic map to represent one, and only one, subject, in order to allow statements to be made about the subject

A topic map covering the domain of opera will thus include topics that represent subjects such as Puccini, *Tosca*, and Lucca.

The collocation objective

Topic Maps employs the nearly synonymous words “topic” and “subject” as very precise terms for the two components of a representation relationship: symbol and referent (Fig. 1).

There is a one-to-one relationship between topics and subjects in the sense that each topic, by definition, represents one and only one subject. Because of this, the terms “topic” and “subject” are often used interchangeably in informal discourse about Topic Maps. The goal of any Topic Maps application is to ensure that each subject is represented by one, and only one, topic. Once this goal (referred to as the “collocation objective”) is achieved, everything that is known (within a given system) about a particular subject becomes accessible from a single point, via the one and only topic representing that subject, and thus the problem of information retrieval is in principle solved.

The means by which the collocation objective is achieved within a system relies heavily on the Topic Maps concept of “identity,” which can also be applied across systems, and thus provides the foundation for “global knowledge interchange”—the potentially unrestricted collation of knowledge from disparate sources. The term “global knowledge interchange” is due to Steve Newcomb.^[15]

Identity

The fundamental issue in achieving the collocation objective is to know when two topics represent the same subject, a situation that can often arise when merging topic maps. When this is the case, the two topics in question must be merged into a single topic that has the union of the characteristics (i.e., names, occurrences, and associations) of the original topics. Once the two topics have been merged, order will have been restored and collocation will once more obtain.

Since the merging of topic maps is intended to be an automated process, the key question is, how can a machine “know” when two topics represent the same subject? The solution adopted in the TMDM is to use explicit, globally

unique identifiers. If two topics share an identifier they are deemed to represent the same subject and merging occurs. Identifiers usually take the form of Uniform Resource Identifiers (URIs) and these come in two flavors: “subject identifiers” and “subject locators.” The TMDM actually allows any kind of “locator notation” to be used, but the interchange syntax (XTM) only supports Internationalized Resource Identifiers (IRIs), an extended form of URIs which permits international characters. A third kind of identifier, item identifiers, are only of interest to implementors of Topic Maps systems. Subject locators were called subject addresses in the first version of the standard.

Subject locators, as their name suggests, are URIs that identify subjects via their location. They can therefore only be used with subjects that have a specific location that can be expressed using a URI—in other words, network-addressable information resources, such as documents (in the broadest sense), newsfeeds, and other data that can be retrieved via Web-based queries. Subjects like this can be identified *directly* via their network addresses.

Most subjects, like Puccini, *Tosca*, and Lucca, do not fall into this category. They reside outside any computer system and are thus in some sense “ineffable”; there is a chasm between the “outside world” in which they exist and the computer system in which they are represented, and this chasm can ultimately only be bridged by human intellect. This is achieved in the Topic Maps paradigm through *indirect* identification using subject identifiers.

A subject identifier is (also) a URI, but it does not address the subject directly; rather it addresses it indirectly, via a “subject descriptor,” which the TMDM defines as an “information resource that is referred to from a topic map in an attempt to unambiguously identify the subject represented by a topic to a human being.” Subject descriptor is sometimes also termed “subject indicator.”

Fig. 2 shows how an ineffable (or “non-addressable”) subject, such as Puccini, can be identified indirectly via a subject descriptor, whose address (<http://psi.ontopedia.net/Puccini>) functions as a subject identifier.

The distinction between direct and indirect identification, which is supported in both the TMDM and the interchanges syntaxes, provides a solution to what has been widely referred to as the “identity crisis” that has caused concern in the Semantic Web community over a number of years.^[16] At the same time, the duality of subject identifier and subject descriptor neatly reflects the dichotomy of the human/computer relationship. Subject identifiers are for use by computers in ascertaining whether or not two topics represent the same subject: if two topics have an identifier in common, they are simply merged; computers have no need to resolve the URI to ascertain exactly what the subject is. Humans, on the other hand, need to be able to do this, because it is they who are ultimately responsible for assigning identifiers; the subject descriptor provides them with an “indication” (through a description, definition, illustration, or whatever) of the subject in question.

Fig. 1 Subjects and topics.

Fig. 2 Subject identifiers.

The concepts of indirect identification using subject identifiers and subject descriptors has been extended into a whole paradigm, known as “published subjects” that seeks to provide an open, distributed solution to the problem of defining and discovering globally unique subject identifiers.^[17]

The TAO of Topic Maps

Having covered the essentials of subjects and how they are represented by topics, we now turn to assertions about subjects.

A topic map is a representation of a set of assertions about one or more subjects. The TMDM defines three kinds of assertion—or “statement”—that can be made about a subject: “names,” “occurrences,” and “associations” (Fig. 3). Associations represent general relationships between subjects; occurrences represent a particular form of “aboutness” relationship in which the participants are an information resource and a subject that the resource is “about”; and names represent relationships between subjects and the labels used by humans to refer to them.

Fig. 3 The TAO model.

The following section describes each of these in more detail.

Associations and roles

Associations express relationships among subjects, for example between Puccini and *Tosca*, or between Puccini and Lucca. They correspond to *See also* entries in a back-of-book index and serve a similar navigational purpose. But there is an important difference in that associations permit the nature of each relationship to be made explicit using “association types”: thus, the relationship between Puccini and *Tosca* can be stated to be of type “composed by,” whereas that between Puccini and Lucca is of type “born in.” The ability to distinguish association types adds precision, provides more information to the user, and improves findability. Association types are themselves subjects and are therefore represented as topics.

A single association may involve any number of subjects. Binary associations (involving two subjects, as in the examples given so far) are by far the most common, and also the easiest to process; they correspond somewhat to transitive verbal constructs in natural language, such as “Puccini composed *Tosca*.” Ternary associations (involving three subjects), while less common, can be useful for relationships that in English might be expressed using a ditransitive verb or an additional thematic role (“*Tosca* kills *Scarpia* with a *knife*”). Associations of higher arity are infrequent; the relationships they might be used to represent (such as that between an opera and multiple librettists) are usually better expressed using multiple binary associations. Unary associations (involving a single subject) are also possible; they often correspond to intransitive verbs and can be used to represent “relationships” that in other modeling paradigms might be expressed using Boolean properties (e.g., “*Turandot* was unfinished”).

Describing a relationship in natural language can give a false impression of directionality: there is no difference, in terms of the basic relationship being described, between the statements “*Tosca* was composed by Puccini” and “Puccini composed *Tosca*.” The difference is rather one of focus. This situation is reflected in Topic Maps by the absence of any formal notion of direction in associations. The order in which topics are specified has no significance; instead, the nature of the subject’s involvement in the relationship is expressed through the concept of “association role.” Each participant in an association is deemed to play a “role” of a certain type. In order to clarify the respective roles of the participants in the example above (and avoid the possible interpretation of Puccini having been composed by *Tosca* instead of vice versa), it must be explicitly stated that Puccini plays the role of (say) “composer,” and that *Tosca* plays the role of (say) “work.” In more precise Topic Maps terminology, “composer” and “work” are “association role types” and, like association types, they are represented by topics (Fig. 4). Exactly what constitutes the roles in this relationship (as opposed to the role types) is less immediately intuitive; one approach is to think in terms of Puccini qua composer of *Tosca* (as opposed to Puccini qua composer of *Madama Butterfly*—or indeed qua husband of Elvira or qua pupil of Ponchielli).

Association types (and role types) are defined by the topic map author according to the requirements of the information, the knowledge it embodies, and the application for which it is intended. There is thus no limit to the kinds of relationship that may be expressed in Topic Maps. However, because of their ubiquity (and utility) in knowledge modeling, two association types are given special status. These are “type-instance” and “supertype-subtype” which carry particular semantics defined in terms of membership of sets of topics called “topic types.” Their special status consists in the following: 1) the standard defines identifiers for these association types (and their corresponding role types) in the TMDM; 2) special syntax is available for type-instance in XTM and Compact Topic Maps Syntax (CTM); and 3) they invoke the application of

Fig. 4 Anatomy of an association.

inheritance mechanisms in certain forms of processing in the query and constraint languages.

Topic types constitute a built-in mechanism for classifying topics and for building a certain kind of hierarchy. That is, type hierarchies—not subject hierarchies of the kind used in subject classification systems, where the subjects do not necessarily (or usually) constitute sets or classes, and the transitivity of type hierarchies does not hold. These can be represented in Topic Maps (as discussed below) but not by using the predefined association types. Topic types for the example topics mentioned so far might be “composer” (for Puccini), “opera” (*Tosca*), and “city” (Lucca). These might in turn be defined as subtypes of “person,” “musical work,” and “place,” respectively.

It is important not to conflate the concepts of topic type and association role type. The former classifies a subject in terms of its “essential being,” whereas the latter merely describes the role it plays in a particular relationship. Sometimes, however, the same topic is used as both a topic type and an association role type. This is because the essential being of a subject is often defined in terms of some kind of relationship: it is precisely because Puccini composed *Tosca* (and many other operas) that he is today regarded first and foremost as a composer; he both *plays the role of* “composer” (in the relationship with *Tosca*, etc.) and at the same time *is a* “composer.” On the other hand, the roles he plays in his relationships with his teacher Ponchielli, his wife Elvira, and his birthplace Lucca, are of different types, namely “pupil,” “husband,” and “person” (Fig. 5). Note that there is almost always an implicit supertype-subtype relationship between the role type and the type of the role playing topic, but there is no general rule for which is which.

Occurrences

Occurrences represent a particular kind of relationship—that of “aboutness” between an information resource and a subject. The resource in question may be very small, such as a string representing a date, in which case it is normally

Fig. 5 Role type and topic type.

included in the topic map and known as an “internal occurrence.” Or else it may be stored externally, because of its size, notation, provenance, or whatever, and referenced via a locator—normally a URL—which corresponds to a page number in a back-of-index (itself a locator for some piece of information relevant to the subject in question). In the latest version of the Topic Maps standard, support is included for specifying the data type (i.e., notation or format) of an occurrence.

Like associations (and association roles), occurrences may be classified by type; typical “occurrence types” in the domain of opera might be “biography” and “date of birth” (for topics of type “composer”); “synopsis” and “premiere date” (for topics of type “opera”); and “map” (for topics of type “city”). Occurrence types provide more information to the user about the nature of the related resource (in contrast to an unqualified list of page numbers in a typical back-of-book index).

Finally, occurrence types—like association types and role types—may be freely defined (again, as topics) to suit the needs of users and applications; there are no predefined types.

Names

Because of their importance in providing labels by means of which humans can refer to and discourse about subjects, names are given privileged status in the Topic Maps model. They may be regarded as a special type of occurrence that carries naming semantics. Like occurrences, names may be typed (and once again, name types are represented as topics), but unlike occurrences they are restricted to a single data type, “string,” in order to ensure that they can always be processed by any system.

It is also possible to specify “variants” of a name, and this facility is widely used to represent sort keys, alternative orthographies, transliterations, misspellings, and so on.

In order to cater for synonyms, the model allows multiple names for the same subject. Distinctions such as language, preferred status, and context of use may be indicated using name types or the concept of “scope” (discussed below).

There is no specific facility in the model for handling homonyms because there is no need: there are no restrictions on what names a subject can have, nor on whether two (or more) subjects have the same name, so homonymy is not an issue as far as the model is concerned. It is left to the application to provide disambiguation based on contextual information available in the topic map: the first line of disambiguation is usually the topic type (“Tosca the opera” as opposed to “Tosca the character”); when this does not suffice, some other association can be used, as with “Puccini’s *Bohème*” (i.e., the *La Bohème* composed by Puccini) as opposed to “Catalani’s *Bohème*,” or “the Paris located in France” as opposed to “the Paris located in Texas.”

Fig. 3 illustrates the basic TAO model and depicts an information layer (below), containing information resources of any and every shape and form, and a knowledge layer (above). The latter consists of (typed) topics and associations, and is connected to the information layer via (typed) occurrences. Identity, scope, and reification (described below) are not depicted.

Ontologies

The term “typing topic” is used informally to refer to any topic that is used (or intended to be used) to type some other construct, whether it be a topic, association, association role, occurrence, or name. Taken together, the set of typing topics in a topic map constitutes a description of the kind of “things” (i.e., subjects) and the kind of relationships that exist in the domain in question (e.g., opera). Viewed in this way, the typing topics can be said to represent the “ontology” of the topic map and the topic map to contain its own ontology. There is no single, broadly accepted definition of the term “ontology” in the information sciences, nor is it defined in the Topic Maps standard, but the informal usage adopted here corresponds very closely to that of John Sowa who defines ontology as a “classification of the types and subtypes of concepts and relations necessary to describe everything in the application domain.”^[18]

Constraints on the types (or classes) that constitute an ontology are defined using TMCL, discussed below.

Additional Concepts

The basic model of (typed) topics that can have names and occurrences and play roles in associations with other topics is very simple and yet powerful enough to express a broad range of knowledge structures—in fact, to make any kind of assertion about any kind of subject—and many current applications of Topic Maps use no more than this core functionality. Additional concepts that provide further expressivity are “scope” (for qualifying assertions in terms of their contextual validity) and “reification” (for making assertions about assertions).

Scope

Knowledge that is aggregated from different sources through the merging of topic maps is likely to contain contradictory statements or have varying relevance in different contexts. For this reason, Topic Maps includes a built-in mechanism called “scope” for expressing the contextual validity of any assertion. Scope is expressed as a set of topics which qualify a statement (i.e., a name, occurrence, or association) and indicate the context in which the assertion represented by the statement may be considered valid. If no scope is explicitly specified, the scope is said to be “unconstrained.”

The interpretation of what it means to be “valid,” and precisely how the scoping topics “indicate” context, is left to the application and as a result the interoperability of scope is limited. However, usage conventions emerging among users of Topic Maps are resulting in increased interoperability. These include specifying the historical applicability or natural language of names and expressing the provenance of occurrences and associations.

Examples of the use of scope in the *Italian Opera Topic Map* include:

- English names of certain operas.
- Provenance of conflicting assertions (e.g., whether the opera *Isabeau* was first performed at the Teatro Colon or the Teatro Coliseo).
- Source of multiple synopses of the same opera (e.g., from Arizona Opera and Opera News).
- Context in which a character has a certain voice type (e.g., Musetta, a soprano in Puccini’s *La Bohème* and a mezzo in Leoncavallo’s).

Reification

Scope can be regarded as a special case (asserting the *contextual validity* of an assertion) of a more general capability (asserting *anything* about an assertion). Assertions represent relationships between subjects, but a relationship can be regarded as a subject in its own right, about which one might want to make further assertions. One way to do this is to represent the relationship as a topic from the outset; another is to “reify” the name, occurrence, or association in question.

Reification (literally “thingification”) in the Topic Maps sense of the term is defined as “making a topic represent the subject of another topic map construct,” in other words, turning a name, occurrence, association role (or even the topic map itself) into a topic in order to make assertions about the thing it represents. This is equivalent to nominalization in natural language, as in “Reagan met Gorbachev in Reykjavík. The meeting took place in October 1986.” In the *Italian Opera Topic Map* the relationship between *Tosca* and Rome (where the opera takes place), is reified as a “The setting of *Tosca* in Rome” in order to provide an appropriate subject for classifying Susan Nicassio’s book *Tosca’s Rome*.

The most widespread use of reification is to reify the topic map itself, thereby creating a topic that can be used for specifying metadata about the topic map (for example, using Dublin Core as discussed below).

THE TOPIC MAPS FAMILY OF STANDARDS

The model described in the preceding sections is specified in detail in the TMDM, which is Part 2 of the ISO standard.^[4] This section provides a brief overview of the

remaining parts (excluding Part 1, which is merely a nonnormative introduction), along with short descriptions of two related standards, ISO 18048 (TQML) and ISO 19756 (TMCL), and a technical report, ISO TR 29111 (Expressing Dublin Core Metadata in Topic Maps).

Syntaxes and Notations

Part 3 of ISO 13250^[5] specifies an XML-based syntax called XTM whose purpose is to enable topic maps to be interchanged between systems. This is the core interchange syntax; it is defined in terms of a mapping to the TMDM and all conforming Topic Maps systems are expected to support it. The original HyTime-based syntax (HyTM) is no longer part of the standard and most tools do not support it. However, because it is rather verbose, XTM is not generally considered suitable for hand-editing, and for that reason other, nonstandard syntaxes were devised (Fig. 6). The most widely used of these are LTM^[19] and AsTMA,^[20] both of which offer compact, text-based notations. A standard text-based notation called CTM^[8] has been defined more recently; a visual notation called Graphical Topic Maps Notation (GTM)^[9] provides a common way of visualizing topic maps and their ontologies, and a canonicalization syntax (CXTM)^[6] supports conformance testing of Topic Maps systems.

The Reference Model

Part 5 of ISO 13250^[7] defines a low-level model called the TMRM which is more abstract and has fewer ontological commitments than the TMDM. Its purpose is to serve as a minimal, conceptual foundation for subject-centric data models such as the TMDM, and to supply ontologically neutral terminology for their disclosure. It defines what is required to enable mapping between different subject-centric data models in order to meet the overall goal of the Topic Maps standards, that each subject has a single location for all the information about it.

The TMRM is defined in terms of proxies consisting of properties which themselves are key/value pairs; the only ontological commitments are two types of relationship: *sub* (subclass of) and *isa* (instance of). In addition to requirements on constraint languages and merging operations, the TMRM includes a path expression language and a mapping to the TMDM, and thereby provides a formal semantics for the latter. It also provides a formal foundation for the related standards TQML and TMCL.

The Query Language

Topic Maps Query Language^[10] provides a standard way of accessing Topic Maps-based information, just as Structured Query Language (SQL) does for relational data and XQuery does for XML data. The initial version provides

access functionality only; later versions are expected to also cover updates. The language currently offers three very powerful and isomorphic ways to express queries:

- All three types of expression can return results in tabular form; `FLWR` expressions can additionally generate XML and Topic Maps output.

Topic Maps Constraint Language^[11] defines a language for expressing ontology-based constraints that a class of topic maps is expected to follow, thus ensuring greater consistency and more predictable results for both users and applications.

- All topics of type “composer” must play the role of “composer” in at least one “composed-by” association.
- Every “composed-by” relationship must involve exactly two topics of types “composer” and “opera,” playing the roles “composer” and “work,” respectively.

Constraint types are defined in terms of the TMDM and their formal interpretation in terms of TQML.

One of the most important aspects of Topic Maps is the ability of the model to represent virtually any kind of knowledge structure or data model. It is this capability—coupled with the ability to merge arbitrary topic maps—that underlies its value proposition: improved information management and enhanced findability through connecting disparate systems and collating information and knowledge from different sources.

Most back-of-book indexes consist of a set of *entries*, arranged alphabetically by *main heading* (sometimes called an “access point” or “subject heading”) and containing zero or more *subentries* (or “subheadings”), *reference locators*, and *cross-references*.^[22]

In Topic Maps terms, every *entry* (except those that only consist of a *See* cross-reference, discussed below)

corresponds to a topic and its *main heading* corresponds to a topic name. *Subentries* are named topics that are related to the topic of the main entry by an association of type “subentry of” (with the role types “main entry” and “sub-entry”). *Reference locators* equate to the locators of (external) occurrences, which would normally take the form of URIs rather than page numbers. *See also* references correspond to generic associations (of type “see also,” or simply “related to”) between topics that represent the respective entries. Finally, *See* references indicate alternate labels for the topics represented by the referenced entries and thus correspond to additional names (of type “alternate name”) for the topics representing those entries.

In some indexes the typeface used for main headings may vary (usually italic in addition to roman, sometimes also boldface). This is a simple form of classification by topic type. Similarly, the use of a different typeface for a reference locator (i.e., page number) is a simple form of classification by occurrence type. Finally, some books contain multiple indexes (e.g., people, places, subjects), which again corresponds to the use of topic types.

Glossaries

A glossary is a list of terms in a particular domain of knowledge along with their definitions. Like indexes, glossaries consist of a set of alphabetically arranged entries, each of which is the equivalent of a main heading. Subentries are not usual, but *See* and *See also* cross-references may occur. Most importantly, each glossary entry contains a definition instead of reference locators.

Using Topic Maps a glossary can be modeled exactly like an index, except that instead of multiple external occurrences, the topic corresponding to each glossary entry will have a single internal occurrence of type “definition.” Thus multiple indexes and glossaries can all be represented within a single topic map.

Thesauri

A thesaurus consists of a set of *terms* and *scope notes*, organized through three kinds of semantic relationship: *equivalence*, *hierarchy*, and *association*. Terms are the names of concepts and thus correspond to topic names; scope notes consist of information pertinent to the topic and therefore correspond to occurrences of type “scope note.”

The equivalence relationship handles synonyms and thus corresponds to topics with multiple names; a *USE* relation would indicate the default (preferred) topic name, while a *USED FOR* relation would indicate a name of type “non-preferred” or “alternate.”

Hierarchy relationships are created by pointing to *broader terms* (BT) and *narrower terms* (NT). Since these are the inverse of each other, they correspond to associations of a single type (“broader/narrower”) which link topics representing broader concepts (e.g., “opera”) to

topics representing narrower concepts (e.g., “aria”). In some thesauri other, more semantically explicit kinds of hierarchical relationship are used (e.g., generic and partitive). These can be represented using more specific association types. Note that the BT/NT relationship, despite being hierarchical, is not the same as the supertype/subtype relationship defined in the Topic Maps standard.

Finally, associative relationships (indicated using *related terms*, RT) equate to *See also* references in back-of-book indexes: they are (nonhierarchical) relationships of no specific type and thus correspond to associations of type “related to.”

Since indexes, glossaries, and thesauri can all be represented by the same model, they can be combined in a single topic map, thus removing potential redundancy. In fact, if the topics that represent index and glossary entries are arranged hierarchically, using associations of type “broader/narrower,” the result is a thesaurus—or possibly multiple thesauri, depending on the number of hierarchies involved. Individual documents or information resources are classified against such a thesaurus by making them occurrences of one or more thesaurus topics.

Taxonomies and subject classification systems are similar to thesauri; they are often somewhat simpler, and they may be more constrained (for example, some taxonomies allow only a strict-type hierarchy based on the generic supertype/subtype relationship), but their representation as topic maps and their practical application is essentially the same.

Faceted Classification

A faceted classification system can be viewed as a set of classification subjects that are grouped along axes called facets. In a topic map this is represented as a set of topics, each of which is related via an association to a topic that represents a facet, and some of which may be organized hierarchically via additional associations.

Bibliographic Records

Bibliographic records are descriptions of information entities, which may be abstract (works) or concrete (documents).^[23] They employ bibliographic languages to describe the attributes of those entities, ranging from the properties of *works* (e.g., author, title, subject), to the properties of *expressions* (translator, editor, language), *manifestations* (publisher, ISBN, format), and *items* (location, call number, condition). Attributes are described as property/value pairs in which the value can be a string, date, integer, or some other data type; or else the name of another entity (such as the author or publisher).

Bibliographic records based on languages of this kind can be represented as topic maps by creating topics to represent each information entity and using statements (names, occurrences, or associations, as appropriate) to represent the attributes. Those attributes with naming

semantics (e.g., title) become topic names; attributes that name other entities (e.g., author, publisher), or that represent terms in an authority file (e.g., a predefined set of media types) become associations and give rise to topics that represent the entities or terms in question; other attributes are represented as either internal or (occasionally) external occurrences.

One widely used bibliographic language is the Dublin Core Metadata Set^[24] which defines a basic set of 15 abstract “elements,” along with a number of “other elements and element refinements,” a set of encoding schemes, and a (media) type vocabulary. An ISO Technical Report^[12] describes how to represent Dublin Core descriptions using Topic Maps.^[25] A similar approach can be used with MARC-21.

In the FRBR (Functional Requirements for Bibliographic Records) model, relationships between works and expressions are represented by an association, as are relationships between expressions and manifestations, and between manifestations and items. Entities of all kinds (including groups 2 and 3) are represented as topics.^[26]

Other Data Models

In addition to the knowledge models described above, most forms of structured data can be represented as topic maps through some kind of schema-dependent mapping. This section looks briefly at how this works with XML (hierarchical), RDBMS (relational database management system), and Resource Description Framework (RDF) (associative) data, respectively.

XML allows the structure of information to be represented in a hierarchy of elements and subelements, with some annotation of elements (via attributes), including linking across (and beyond) the element hierarchy. The semantics of the element and attribute types are vocabulary dependent, but they can be extracted and represented as a topic map using techniques described by Pepper and Garshol^[27] and Garshol and Bogachev.^[28]

In the entity–relation (ER) model, entities equate to topic types and relations to association types, while attributes correspond to names, occurrences, and identifiers (Fig. 7). When mapping relational data to a topic map, each row in an entity table (for example, “Organizations”) gives rise to a topic of the corresponding type (in this case, “organization”); each column can result in an identifier, name, occurrence, or association, depending on whether the data is an ID, a string with naming semantics, some other kind of string data, or a foreign key reference, respectively. Each row in a relation table (for example, “Employment”) results in an association of the given type (here, “employed by”) whose role players are found via the foreign key references.

The associative (graph-based) model of the RDF is much closer to the Topic Maps model than XML or ER, and this means that RDF data can be used in Topic Maps systems with almost no mapping.^[29,30] It has also been demonstrated that data conforming to EXPRESS data models can be transformed to Topic Maps with relative ease, although this work has not yet been published. The EXPRESS modeling language is part of the product data standard STEP (ISO 10303).

The screenshot shows the Omnigator web application interface. The main content area displays a topic map for "Puccini, Giacomo". The interface includes a navigation bar with links like "Home", "Manage", "Website", "Support", and "About". Below the navigation bar, there is a search bar and a list of topics. The main content area is divided into several panels:

- Untyped Names (3):**
 - Puccini, Giacomo
 - Giacomo Puccini - Scope: Normal form
 - Puccini - Scope: Short name
- Associations (18):**
 - Born in: Lucca
 - Composed: La Bohème, Edgar, La fanciulla del West, Gianni Schicchi, Madama Butterfly, Manon Lescaut, La rondine, Suor Angelica, Il Tabarro, Tosca, Turandot, Le Villi
 - Died in: Brussels
 - Exponent of
- Subject Identifiers (1):**
 - http://en.wikipedia.org/wiki/Puccini
- Internal Occurrences (4):**

Fig. 7 A topic page in the Omnigator.

AREAS OF APPLICATION

As the preceding section has shown, virtually any form of structured data, information, or knowledge can be represented as a topic map. This is not to suggest that all information should be maintained directly in Topic Maps form. A more common scenario is to use Topic Maps as a meta-model for integrating portions of data that originate from different systems (some of which may be Topic Maps-based). The procedure is to generate multiple topic maps from disparate sources and then merge them to provide a unified view of the information gestalt.

It is the flexibility of the Topic Maps model and the robustness of the identity paradigm on which merging is based that provide the clue to identifying application scenarios in which the technology can excel. Another quality of Topic Maps is its intuitiveness: experience shows that the TAO model is very easy for users to grasp, presumably because it derives from artifacts, such as indexes, that humans have used for centuries to locate and manage information. The associative nature of the model is also a factor in this, reflecting as it does how people think, learn, and store information in their own “semantic memories.”

Most applications of Topic Maps fall into four broad categories: enterprise information integration (EII), KM, e-learning, and Web publishing.

From the EII perspective, Topic Maps offers an out-of-the-box “meta-model” for integrating information, and a powerful identity mechanism for enabling subject-based merging. A topic map can provide an aggregation layer on top of existing information systems, or function as a

hub for transferring data between systems, or both. Either way, Topic Maps removes the need for costly point-to-point system integration.

From the KM perspective, Topic Maps provides—arguably for the first time—the ability to really capture and manage some degree of *human knowledge*—not just information—in a standards-based form, enabling it to be shared and reused across departments, organizations, and systems. The topic/association layer constitutes a distributable and queryable knowledge base, which can be tightly coupled with content management systems via the occurrence axis.

In the domain of e-learning, Topic Maps has particular relevance, not just because of its strengths as a content management technology, but because it bridges the gap between information and knowledge.^[31] In Norway, successful experiments have been conducted in which school students are encouraged to create topic maps to record what they have learned, and the National School Curriculum itself now has its definitive expression in the form of a topic map.^[32]

One application whose potential is as yet largely untapped is the use of Topic Maps as the foundation for digital libraries. At its most basic, a digital library can be defined as digital content that is organized along bibliographic principles. It requires technology of a new kind that is attuned to the needs of digital information while at the same time supporting bibliographic principles and practices. Topic Maps is just that. An early example of the application of Topic Maps to this purpose is the award-winning New Zealand Electronic Text Centre (Fig. 8).^[33]

Fig. 8 A Topic Maps-based digital library.
Source: <http://www.nzetc.org>.^[33]

In all of these applications, and many others besides, the World Wide Web provides the most important channel for disseminating information, via Web sites, portals, and intranets. Despite in some ways predating the Web, Topic Maps has proven to be well-suited to this form of publishing: the TAO model offers a readymade “information architecture” in which each page is devoted to a single well-defined topic and contains information collated from the names and occurrences of that topic, with intuitive navigation paths between pages generated from associations between topics. An increasing number of second and third generation Web sites are currently reorganizing their content into topic maps, and a product such as the *Omnigator*,^[34] which is a Web-based browser for topic maps (Fig. 7), is essentially a tool for creating “instant Web sites”: when it loads a topic map, the result is a bare-bones, out-of-the-box Web site.

CONCLUSION

Topic Maps is a paradigm-shifting technology. Through its emphasis on the centrality of subjects, rather than documents or applications, it presages a radically new way of using computers to manage information and knowledge, dubbed subject-centric computing.

The key strengths of Topic Maps are a flexible model that can represent any kind of data structure; a robust model of identity; the ability to merge arbitrary topic maps; a well-defined syntax for exchanging topic maps between systems; status as an ISO-approved international standard; and a vibrant and committed user community. Witness the annual user's conference in Oslo, the annual academic conference (Topic Maps Research and Applications, TMRA) in Leipzig, the Web site <http://www.topicmaps.com>, various mailing lists, etc.

Topic Maps is particularly well-suited for integrating information from disparate sources, bridging the gap between information and knowledge, and acting as an information architecture for Web-based information delivery.

Tunisia: Libraries, Archives, and Museums

Ali Houissa

Olin Library, Cornell University, Ithaca, New York, U.S.A.

Abstract

This entry provides factual data and background on the development and current state of libraries, archives, and museums in Tunisia. Emphasis is on the more-significant components of these sectors historically and culturally. The development of cultural institutions since Tunisia became independent and important legislation concerning these institutions are addressed in some detail. The conclusions point out that despite considerable investment in cultural and information infrastructure and services, there remain considerable hurdles to overcome for this emerging albeit studious country.

INTRODUCTION

Tunisia is a compact but kaleidoscopic North African country of 10 million located on the southern shore of the Mediterranean Sea, wedged between Algeria and Libya. Its strategic position and climate have made it a coveted land since ancient times. Vestiges of past civilizations remain visible testimony to the country's rich and diverse history, stretching back 3000 years. Culturally, modern Tunisia represents a rich admixture of native and foreign influences. While predominately Arab and Muslim these days, the country has been deeply imbued with diverse civilizations, including Berber, Phoenecian, Roman, Arab, Ottoman, and European. Contemporary Tunisia retains numerous traces of its long and diverse past. From the flourishing Roman era that lasted six centuries and witnessed the advent of Christianity, some of the best Roman mosaics in the world still survive. Rich Islamic architectural patchwork coexists with vestiges of French colonial influence. As a token of the country's rich patrimony, Tunisia is home to at least seven monuments and sites on the UNESCO World Heritage list. Rivalries between European interests over Tunisia in more-recent centuries culminated in a French invasion in 1881 and the establishment of a protectorate regime that lasted until 1956 (Fig. 1).

The newly independent republic has since pursued modernizing social policies, giving high priority to universal education and establishing rights for women unmatched by neighboring nations. As the Arab country that most wants to be seen as modern, Tunisia has taken a moderate stance domestically as well as in its foreign relations and is now among the region's emerging countries being the one with the fastest economic growth. More than 20% of the Tunisian government's annual budget goes to education and cultural institutions such as libraries, archives, museums, and arts centers. The following sections highlight Tunisia's most significant achievements

and infrastructures in the fields of library and information science, archival systems, and museology.

LIBRARY AND INFORMATION PROFESSIONS, SYSTEMS, AND SERVICES

Historic Background

Libraries and books in preindependent Tunisia

Perhaps the oldest, continually existing library in Tunisia is that of the Grand Mosque of Qayrawan (also spelled Kairouan) and its attendant, now defunct, university, which is considered "amongst the first universities throughout history."^[1] Tunisia is practically a bilingual country; French is widely used in daily life besides Arabic. In this study, transcription and romanization of Arabic is based largely on the ALA-LC Romanization Tables: Transliteration schemes for non-Roman scripts (<http://www.loc.gov/catdir/cpsd/romanization/arabic.pdf>). As the country's holy Muslim city and the site of the oldest religious shrine in western Islam, Qayrawan was founded in 670 A.D. and had developed into a great center of learning. By the tenth century its religious, cultural, and scholastic influences reached parts of Africa, Europe, and Asia, attracting students and scholars from afar. The Grand Mosque has preserved some of the remnants of its great intellectual apogee and memory of its scholars through books and documents they wrote or assigned others to write. Many of these unique documents were part of the curriculum taught then and were considered "the largest and best known collection in the Arab Islamic world."^[2] The Grand Mosque's library included mostly religious manuscripts and Korans written in large part on parchment. Following the sack of the city in the eleventh century, much of the library's collection was lost. Many of the surviving works are now preserved at the National Library

Fig. 1 Map of Tunisia.

in Tunis. A handwritten catalog containing a quite detailed description of the contents of the Grand Mosque's library, compiled in 1293 A.D., was uncovered in the mid-twentieth century (Fig. 2).^[3]

Another cultural and learning hub in Qayrawan was Bayt al-Hikmah (House of Wisdom, or House of Knowledge), a pioneering gathering of scholars-cum-translators whose principal role was to render into Arabic what had survived of the mathematical, scientific, and philosophical legacy of the ancient world^[4] that had been lost to medieval Europe. Established at the end of the ninth century, Bayt al-Hikmah of Qayrawan rivaled its famous counterpart in Baghdad in the study of medicine, astronomy, engineering, grammar, and translation.^[5] A crucial

contemporaneous development tightly linked to books and knowledge diffusion that should be mentioned is papermaking and the establishment of paper mills all over the Islamic provinces by the eleventh and twelfth centuries. In North Africa the work of eleventh century Prince al-Mu'izz ibn Badīs al-Zīrī, a patron of the arts, included a brief account of medieval papermaking in his treatise *Umdat al-Kuttab* (Staff of the Scribes and Implements of the Discerning, or, The Pillar for Penmen), the only medieval Arabic work on the art of the book to survive.^[6]

Other Tunisian cities' grand mosques also had library collections, the remnants of which can still be found today. The Zaytūnah Mosque, in Tunis, which was once also one of the oldest universities, has a considerable library.^[7] Large numbers of its manuscripts and books were housed in the Zaytūnah's al-Abdalīyah Library. Although not the oldest of the country's libraries, it was possibly the richest of all. It had several collections totaling in the tens of thousands. Most rulers of the Hafsid dynasty of the thirteenth to sixteenth centuries in Tunis vied with each other for the prestige associated with building the collection, which at some point exceeded an estimated 100,000 volumes, including rare manuscripts.^[8] When Spanish troops invaded and occupied Tunis between 1534 and 1574, many of the precious books and manuscripts in its libraries were looted or destroyed. The succession of Turkish dynasties that subsequently expelled the Spanish restored and expanded the Zaytūnah Grand Mosque and its affiliated libraries.^[9] The nineteenth century country's ruler, the bey of Tunis, Ahmad Pasha I, was the patron and promoter of the Ahmadiyah Library and added large numbers of books to its collection.^[10]

Independent Tunisia

Tunisia had generally enjoyed a period of relative political and social stability from the late sixteenth century until the establishment of the French Protectorate in 1881. That was also an era of idle cultural, intellectual, and scientific life. French colonial rule shook the country and brought many important social and political changes. Not long after the end of the World War II, France felt compelled to make some concessions to Tunisia, a process that culminated in the end of French colonial rule in 1956 and the establishment of a republican-presidential style regime. The French legacy, however, endures to date and is visible in many aspects of daily life. Since the earlier years of independence, the new regime's top priorities have been to reform education and encourage culture, and it has set aside a sizable portion of its operating budget for that purpose. Schooling became compulsory, free, and state-guaranteed between the ages of 6 and 16. By the 2006 school year, primary, secondary, technical, and vocational schools had a total enrollment of close to 2.5 million. The number of institutions of higher education increased from a couple at independence to 178 in 2006 with an estimated

Fig. 2 The seventh century Qayrawan Grand Mosque.

enrollment of 365,000 students, 56% of whom were female students.^[11] The constitution of the new republic provides for freedom of the press and of speech. The Tunisian press began publishing in the second half of the nineteenth century and flourished under colonial rule. It followed the French model, by which newspapers were highly editorialized and represented the official position of the government. That tradition has continued in independent Tunisia. The country now has 22 daily newspapers for an aggregate circulation of 375,000 copies, over 210 national weeklies and monthlies with a circulation close to 900,000, and more than 700 foreign magazines and newspapers.^[12] The Internet reaches over 953,800 subscribers, a tenth of the population in 2005.^[13] Tunisian book publishing, generally divided between Arabic and French, is a relatively small industry of approximately 125 publishers.^[14] Book production has been on the increase over the years, from just a handful of titles published in the early years of independence to about 1500 in 2006. However, for 65% of those titles, print runs rarely surpass 500 copies.^[14] Tunisia's most prestigious literary distinction is the "Comar d'Or" (Golden Comar)—from the name of a Tunisian philanthropic insurance agency that organizes and funds the event every year. The country's library system is diversified and relatively well established compared to other Arab and African nations. Overall, its information and cultural infrastructures, as spotlighted in the following sections, are impressive for a country of this size.

National Library and Information Services

Dār al-Kutub al-Waṭanīyah (Bibliothèque nationale, <http://www.bibliotheque.nat.tn/>)

The National Library of Tunisia (Fig. 3) is an administrative public establishment under the Ministry of Culture

and Safeguard of Patrimony. Its origins as a national repository go back to 1885, when it was the *Bibliothèque française*, (also *Bibliothèque française de Tunis* and *Bibliothèque générale*). Its first holdings consisted mainly of the private collection of Charles Tissot, a French diplomatic officer and researcher in Tunis at the time. They were gradually enriched with thousands of Arabic books and manuscripts transferred from the Grand Mosque of Tunis and other madrasa schools. In 1910 the library was relocated to a building in a sector of the old city called al-ʿAṭṭarīn, which served since 1813 as one of five military barracks in the capital. Later, under French rule, it was used as headquarters of the Antiquities Administration (*Direction des antiquités*). It became known then as the *Bibliothèque française de Tunis*. Upon independence in 1956, the library started to function as the de facto national library. Its mission was to build collections in all formats, especially of works published in Tunisia, which

Fig. 3 The new building of the Tunisian National Library.

must by law be deposited there; conserve them; and make them available to the public. It functioned as a research library with a strong focus on the humanities. The introduction of mandatory legal deposit in 1956 required commercial publishers to provide copies of all published books to the National Library. In 1967 and by virtue of a government decree, all “public manuscripts” held in public libraries, mosques, and zawiyahs (religious shrines) were ordered to be transferred to the National Library.^[15] The library currently has over 2 million monographs, 40,000 manuscripts, 13,000 periodicals (titles), and 5000 maps.^[16]

The library’s main publications are two annuals: *al-Kitāb al-Tūnī: al-Bībliyūghrāfiyā al-Waṭanīyah Waṭanīyah* = *Bibliographie nationale tunisienne* = *Le Livre tunisien* and *al-Fihris al-‘Āmm lil-Makḥaṭūṭat* = *Catalogue général des manuscrits*. It also issues an annual bibliographic list of university theses and dissertations and occasionally puts out special bibliographies. Its online catalog is actually the previously mentioned Tunisian National Bibliography and is searchable in Arabic and Latin characters for titles published in 1997 and later. Bibliographies of the years 1997–2002 are now accessible online (http://www.bibliotheque.nat.tn/asp/index_ar.htm). *Tunisiana*, a Latin-script-only database, gives access to entries for documents published in Tunisia prior to 1966. There are several projects under way concerning the conversion into PDF of the full text of periodicals and serials (examples: *al-‘Alam al-Adabī*; *Shabab*; *al-Mabahith*; *al-Ra’id al-Tunī*) as well as a number of manuscripts and original legal texts (Tunisian Constitution, the Personnel Status Code). The National Library, which began the automation of its bibliographic data in 1997, has undertaken the retrospective conversion of the old catalogs and files dating back to the end of the nineteenth century. Its multilingual catalog includes books published between 1500 and 1830. An in-house facility for retrospective conversion was set up in 2002. The ISBD and UNIMARC standard formats for recording bibliographic data were introduced in the 1980s. Bibliographic databases have been established using:

- UNESCO’s common communication format (CCF), a standard for creating bibliographic cataloging records developed by UNESCO in 1984 for nonlibrary agencies. Common communication format offers a simple platform for machine-readable bibliographic data for the benefit of developing nations. Unlike MARC, CCF specifies no rules for description, permitting minimal records and groups of fields called record segments that allow for relationships between fields and records.
- UNESCO’s CDS/ISIS, a bibliographic information management software to develop catalogs of manuscripts and old documents. This free library information storage and retrieval software for microcomputers was introduced in 1985.

- MINISIS, an integrated multiplatform software, for information production and management in a variety of languages and character sets.

By the mid-1990s the National Library started considering the acquisition of a MARC-format-compliant, multiscript-capable, integrated library system (ILS). In 2005 the Horizon integrated library system, developed by Ameritech Library Services and Arabized by a Saudi Arabian company, was chosen as the ILS system. The National Library has adhered to the ISBN system since 1988. It started using the CDS-ISIS bibliographic software in 1991 to catalog legal deposit items to be listed in the Tunisian National Bibliography. For all ongoing retrospective conversion projects, UNIMARC is the format used. The old Roman script catalog (up to 1966) with 200,000 bibliographic records was converted between 2001 and 2005; the old Arabic manuscripts catalogs were automated in 2005. The conversion of the more-recent Roman script catalog (1966–1998) started in 2006.^[17] To complete the picture, a national authority file using UNIMARC Authority format was planned for 2006. In its effort to build what is hoped will be the national virtual library, the National Library embarked on digitizing first the “main national heritage works,” such as manuscripts and older print documents, books, periodicals, and bibliographies, many of which are also being made available as CD-ROMs. The National Library opened to the public in February 2005 in a new location in downtown Tunis. The new building covers 35,000 m² of space and includes a spacious room for reading documents, a conference room, a laboratory, an exhibition hall, a visitors’ gallery, a restaurant, and a 10,300 m² parking lot.

Legislation Concerning Libraries

Legal deposit and copyright

Modern Tunisia inherited from its former French colonial occupier (1881–1956) a political structure and a cultural environment that are still visible everywhere. The French instituted the first press and publishing codes during colonial rule, and after independence in 1956, the government enacted legislation related to media and cultural institutions, many of which were drafted on the basis of the French “Depot Legal” system. Embedded in the Tunisian Press Code,^[18] the system of legal deposit impacts all sorts of publications. Publishers, distributors and printers, public agencies, and university institutions must submit copies of all printed material to the Ministry of Culture, the National Library, the Ministry of the Interior, and the Public Prosecutor’s Office. The categories of documents subject to legal deposit include official and unofficial publications as well as academic publications. Upon deposit of the copies, a receipt (*récépissé*) is issued by the Ministry of the Interior; only then can the publications be

produced and distributed. Foreign publications must get clearance from the Ministry of the Interior before distribution in the country. The Press Code was amended in 1988, 1993, and 2001. The more-recent amendments removed punitive measures that had included prison sentences and payment of fines for publishing without a legal permit. In theory, by virtue of these amendments, no newspaper can be suspended without a court decision. A 2005 amendment to the Press Law abolished the legal deposit process altogether, including related sanctions and punitive measures.^[19] Some jurists and observers have questioned such legislation and the sincerity of the recent reforms to abolish the legal submission process.^[20]

Tunisian law provides for intellectual property rights and copyright protection, including publication procedures, the transfer of rights and permission to photocopy.^[21] But, as elsewhere, enforcement is an ongoing problem.

Statutes and legislation concerning libraries and librarianship

Since independence, administrative oversight of Tunisian libraries has shifted several times among government agencies and ministries. Libraries and library staff and professionals are largely part of the public service, and their status is covered by provisions of legislation governing Tunisia's public administration. Laws addressing specific library entities, the jurisdictions they fall under, their funding, organization, and governance have been enacted and amended over the years. The following decrees and laws are the more significant:

- Decree no. 92-1353, July 20, 1992. Fixing the conditions and requirements governing nominations of library directors at universities and institutions of higher education and research. The law covers compensation, benefits, indemnities, and advantages accorded to appointees.^[22]
- Decree no. 94-559, March 15, 1994. Concerning structure and organization of the National Library and outlining its areas of responsibility.^[23]
- Decree no. 99-2762, December 6, 1999. Addressing the particular status of all personnel working in libraries and documentation centers that are part of the public administration.^[24]
- Decree no. 79-756, August 1979. Concerning mission, description, and organization of the National Library.^[25]
- Decree no. 79-698, August 1979. Regarding creation and transfer of positions at the National Library.^[26]
- Decree no. 75-254, April 1975. Addressing the status of management staff (cadres) of libraries, documentation centers, and archives.^[27]

All statutes and decrees consulted for this study were published in French in the official *Tunisian Gazette*, *Journal officiel*, and are available in digitized format in the

online database of the Centre national universitaire de documentation scientifique et technique: <http://www.cnudst.rnrt.tn/wwwisis/jort.06/form.htm>.

Academic Libraries

There are currently 178 institutions of higher education, among them 13 universities (Ezzitouna Islamic University, Manouba University, Tunis University, Tunis El Manar University, University of 7 November at Carthage, Jendouba University, Sousse University, Sfax University, Gabes University, Kairouan University, Monastir University, Gafsa University, and the Virtual University), in addition to the 24 Higher Institutes of Technological Studies (ISETs), 6 Higher Institutes of Teacher Training (ISFMs), and about 20 licensed private higher education institutions.^[28] One hundred fifty-five institutions are under the supervision of the Ministry of Higher Education, and 23 others come under shared supervision of that and other ministries (Communication and Technologies; Youth, Agriculture, Social Affairs, etc.)^[29] The student population in 2006 was estimated at 430,000.^[30]

Each university has a central library, bibliothèque universitaire centrale (BUC), responsible for all institutional information needs. All central libraries are part of a national electronic library network of BUCs in the country.^[31] The total university libraries holdings is estimated at over a million titles, not including 100,000 published and unpublished theses and dissertations.^[30]

The National University Network, Réseau national universitaire (RNU), is a project to create an online academic network connecting all institutions of higher education and research establishments in Tunisia to each other and to the Internet. By 2007 the number of RNU users was estimated at 221,924. The computer center al-Khawarizmī (Centre de calcul el Khawarizmi, CCK) was designated the Internet service provider for all institutions of higher learning in 1997. Included among its services are Web hosting, electronic mail, file transfer, database development and management, faculty training, and hosting of the university library system union catalog, BIRUNI (Bibliothèque Informatisée pour la Rénovation UNiversitaires, previously known also as Bibliothèque des Ressources UNiversitaires). It was initially launched in 1996 and was envisioned as a virtual library project using VIRTUA, the ILS by VTLS. The BIRUNI union catalog's main page functions as a gateway for searching all university catalogs. It also provides clustered links to Tunisia's university library catalogs by region: "Catalog of the North" "Catalog of the Center" "Catalog of the South." Although the site lists the categories "electronic periodicals" and "online theses," at the time of this writing the links to them are not active. Access to fee-based electronic resources and online databases is through the National Academic Center for Scientific and Technical

Information (Centre national universitaire de documentation scientifique et technique, CNUDST).

Centre national universitaire de documentation scientifique et technique (CNUDST, <http://www.cnudst.rnrt.tn>)

The center was created in 1979 as a unit of the Ministry of Higher Education with the broad mandate to support the acquisition of, and access to, scientific and technical information for the Tunisian research community (law No. 78-59 of December 29, 1978, and Decree No. 99-2241 of October 11, 1999).^[32] Centre national universitaire de documentation scientifique et technique holds the legal deposit right to receive one copy of every publication issued by institutions of higher education and scientific research in the country and is responsible for acquiring all such scientific documents by Tunisians in French universities. It houses the “virtual library of research” and provides gateway access to electronic resources consisting of subscriptions to databases and full-text online scientific periodicals. Centre national universitaire de documentation scientifique et technique negotiates database licenses on behalf of higher education and research establishments. Moreover, the center has developed, on its own, four freely accessible, online bibliographic databases:

- TUNIDOC. Lists documents, monographs, theses, articles, etc. relating to Tunisia or written by Tunisians. There were 37,129 multilingual, multidisciplinary entries as of April 2007.
- TUNIPER. A union catalog of serials and periodicals available in 130 Tunisian institutions. As of February 2007, 17,739 titles were listed.
- JORT [*Journal officiel de la république tunisienne*]. A bibliographic and full-text, online database of most laws, legislation, and other legal statutes published in the Official Journal of the Republic of Tunisia since January 1, 1956. As of March 2007 it contains 55,235 entries in Arabic and French.
- BDRGI (Base de données des ressources gratuites sur Internet). A selected online guide to electronic resources available on the Internet.

EUMEDCONNECT

This is a project funded by the European Commission to provide dedicated Internet connections between the research and educational communities of the Mediterranean region. It will link the national research and education networks of Algeria, Cyprus, Egypt, Israel, Jordan, Lebanon, Malta, Morocco, the Palestinian Authority, Syria, Tunisia, and Turkey to Europe through the pan-European research and education network called GÉANT. The potential benefit from this initiative for Tunisia's

research and education sector is dedicated connectivity to research in state-of-the-art research information databases and facilities in European research institutions. DANTE, the “Delivery of Advanced Network Technology to Europe,” runs the circuit that links Tunisia to the network through Italy in coordination with Réseau fédéré de la recherche (RFR), managed by the Tunisian Secretary of State for Scientific Research and Technology.

Public Libraries

There are about 380 public libraries throughout the country,^[33] supervised by the Ministry of Culture (Ministère de la culture et de la sauvegarde du patrimoine). The Public Libraries Service (Direction de la lecture publique) in that ministry, founded in 1965, administers almost all public Tunisian libraries and publishes an annual Bulletin. Estimated total library holdings as of 2005 were about 5 million books, but only 60,000 of them are unique titles. Libraries are divided as follows:

- 311 public libraries, of which 305 have children's branches.
- 24 regional libraries and 28 mobile libraries.

In 2004 there were 5,230,179 public library visitors, almost half of them children and young adults. Of that number only 167,000 were registered users, who checked out 3,760,059 books.^[34] Public libraries charge an annual fee, the equivalent of U.S. \$1 for adults and half of that for youths, for use of all library services including the Internet.

Most public libraries that have been using card catalogs and traditional methods to manage their collections are becoming automated. Increasingly, modern information technologies, such as integrated library systems, computer catalogs, and library networks, are being introduced. In 1998 a pilot public library, the Médiathèque Ariana, went live with a biscript (Roman–Arabic) ILS based on UNIMARC. In 2004 the French government funded a project to promote public reading and the public library sector. One of its aims was to computerize the Ministry of Culture's Public Reading Service (Direction de la lecture publique) as a first step toward full automation and networking of the public libraries countrywide. The funding also includes acquisitions of book materials, especially for youth, and covers staff education and training at the Tunisian Higher Institute for Documentation (Institut supérieur de documentation) and in France.

There remains room for improvement when it comes to the role public libraries play in most people's lives; there is a lack of well-established reading habits, and books continue to be viewed outside school curriculums as unaffordable luxury items. But a vast action-program launched in 1997 with the aim of gradually connecting public libraries to the Internet has been a promising development.

School Libraries

Despite limited resources, the Tunisian government has allocated, in the decades since independence, about 7% of the gross national product (GNP) to education, one of the higher such ratios in the world. In 1991 a new education-system reform law^[35] was passed instituting compulsory and free schooling for children up to the age of 16 and stipulating that public education of all children of school age is a “right” and an “obligation.” As a result, enrollment reached over 99% among 6-year-olds. It is worth noting that, based on the available government statistics, regional disparities of access to schools persist: coastal and north-eastern regions continue to achieve the best schooling rates compared to rural areas in the northwest and southwest.^[36]

The rate of enrollment in primary education for children 6 to 11 years old was 98% during the 2005/2006 school year, for a total of 1,120,424 pupils in the primary cycle of public schools (“Premier cycle de l’enseignement de base,” 6 years) and 571,986 in the second cycle (“Deuxième cycle de l’enseignement de base,” 3 years). Enrollment in secondary public schools (enseignement secondaire) during the same year was 503,531.^[37] Tunisian primary and secondary schools have strong language programs, allocating more time to foreign language instruction than most European countries (29% of total instruction time in Tunisia in contrast to 10% in Europe). French is introduced at age 8, English at age 10, and a third language in secondary school.^[38] All school libraries in primary through preparatory and secondary schools are, in terms of human resources, administration, and funding, under the purview and centralized supervision of the Ministry of Education and Vocational Training, Service of Means and School Libraries (Ministère de l’éducation et de la formation, Service des moyens et des bibliothèques scolaires).^[39] The ministry acquires books through group purchases, a centralized process established in 1991.^[40] There are no available surveys of school library holdings. Secondary schools tend to have more libraries than primary schools; the concept of library in the latter category, if it ever applies, should be used loosely. School directors have small discretionary budgets for incidental expenses, including book purchases, and many accept additional supplies from other community sources. Other than textbooks, most titles, for the use of students and teachers, are in Arabic and French and cover literature, philosophy, science, technology, and economics. School libraries are not well funded and are rarely considered the focal point for learning in Tunisian schools. As a consequence, they are not well stocked. The limited commitment to school library service reflects a salient lack of learning opportunities outside the formal classroom, attributed quite often to limited funding. When it comes to the extras outside the classroom programs, however, libraries compete with sports, music, etc. for time and funds. Moreover, the

textbook is perceived as a complete book—other classroom teaching materials complete the picture.

The advent of the Internet, its spread throughout educational institutions, and its general popularity has been a mixed blessing for libraries and reading. In fact, school libraries (and all kinds of public libraries) are increasingly called “médiathèques,” that is, basically media centers offering a range of learning resources from textbooks, dictionaries, and encyclopedias to media materials, audio-visual aids, and increasingly the Internet—hardware and connection offered for free to all schools, courtesy of the government and the Ministry of Education.

The Tunisian government has invested heavily in computer training, technology, and online services and has succeeded in providing all secondary schools and tertiary institutions with computers, IT laboratories, and Internet connections. It has been working on a program that will bring all primary schools technologically up to speed by 2006. In addition, the Education Ministry has established a Virtual School to support distance learning and has set up EduNet (<http://www.evt.edunet.tn/indexan.htm>), an educational gateway and network linking Tunisian elementary and secondary schools to the Internet. EduNet provides a variety of Web services such as general information, e-learning sites, e-mail, databases, etc. By the late 1990s, EduNet had connected almost 500 primary, all 400 secondary, and over 50 technical schools.

In 2002 the ministry launched the Educational Virtual Library (Bibliothèque virtuelle éducative (BVE), presented as a tool linking the education community to online resources useful for information research and supplementing what is available in print, including: JSTOR Journal Storage, *Blackwell Synergy*, IEEE’s *POP ALL*, Proquest’s *ABI/INFORM Global*, Elsevier’s *Scopus*, and Thomson ISI’s *Web of Science*. The system’s gateway (<http://www.bve.edunet.tn/fr/index.php>) is bilingual, French and Arabic, and allows online searching by Dewey classification numbers.

Outside the Tunisian school system there are a number of international schools, often affiliated with foreign organizations or countries and their cultural missions. Worth mentioning is the American Cooperative School of Tunis (ACST) which, since 1959, provides elementary, middle, and high school American education. The school offers a curriculum that essentially follows the guidelines of U.S. public schools adapted to the needs of international students and a program leading to a U.S. academic diploma and the International Baccalaureate diploma. At the beginning of the 2006/2007 school year, enrollment was 494 (pre-K to grade 5: 264; grades 6–8: 114; and grades 9–12: 116). The 10-acre campus includes an administrative pre-school building containing an elementary library with an amphitheater and elementary computer lab. For the upper school there are computer labs, art rooms, and the main library with more than 12,000 volumes and a computer research area. The ACST Middle and High School Library

sets up monthly displays of books, artifacts, and interactive materials surrounding a current topic.

Special Libraries

Tunisia has a number of wide-ranging special libraries maintained by associations, government departments and services, research institutions outside universities, learned societies, NGOs, etc. Their collections are, as is usually the case for this type, in a specific field such as agriculture, law, social sciences, medicine, economics, and engineering. Collections and services are for the most part designed to provide for the information needs of their primary users and other specialists in the respective field and to a lesser extent the needs of members of the public at large. Some of the largest special libraries are those under the jurisdiction and direct supervision of government ministries.

In 1977, a national commission for documentation and information (Commission nationale de documentation, CND) was charged with developing a plan for setting up a national information system network structured by sector (libraries, documentation centers, archives, etc.) and connected to international information networks. Each component of that system was to be called a Centre national pilote sectoriel, CNPS (national specialized pilot center). Each of the resulting 12 CNPSs is assigned to build a network in its respective sector of specialty. Together, all the CNPSs form Réseau national d'information et de documentation (RNID), the national information and documentation network.

Generally, technical and scientific information and documentation is the responsibility of three main bodies: Centre de documentation nationale (CDN); Centre national universitaire de documentation scientifique et technique (CNUDEST), described in a previous section; and Centre national de documentation agricole (CNDA).

Centre de documentation nationale (CDN)

The National Documentation Center collects and preserves all documents and information on cultural, political, social, or economic issues available anywhere and directly relating to Tunisia. Created in 1966, the status of the CDN is defined and governed by a 1982 Presidential Decree^[41] as the cornerstone of the national information network. It currently has a library of about 8,000 monographs, 2,400 periodicals, 10,000 press documents ("dossiers de presse"), and 50,000 photographs,^[42] most of them accessed through the center's computerized database, TANIT. It has developed a guide to information services in Tunisia and created a number of databases including ITARAT, on governmental structures and related information, and ASSO, on associations. The CDN is an IIP focal point for UNESCO (Intergovernmental Informatics Program). The CDN is also the subregional focal point for the Francophone database Banque

internationale d'information sur les états francophones (BIEF), and its program named "La Francophonie," a network of focal points in 52 Francophone member states.

Centre national de documentation agricole (CNDA)

The National Center for Agricultural Documentation was conceived under the Ministry of Agriculture as a central hub for collection and dissemination of current and retrospective agricultural information and data. It publishes TUNAGRI, the national agricultural bibliography, and CARIST, a quarterly bulletin that covers current research information, reference documents, and agricultural facts and figures, as well as places, names of agricultural scientists in the country, and other online resources (market research, agricultural politics, etc.). It also has a legal resources database, JORTAGRI, for texts of legislation, laws, decrees, etc. relating to agriculture (<http://www.onagri.nat.tn/Default.htm>). The center also provides gateway access to automated agricultural databases. The AGRINET, managed by the Institut de la recherche et de l'enseignement supérieur agricole (IRESA), connects 14 institutions of higher education in agriculture as well as 7 regional research centers. It also connects the various departments of the Agriculture Ministry as well as its regional representations (Commissariats régionaux) throughout the country. The CNDA is affiliated with the international agriculture system, AGRIS, the international information system for the agricultural sciences and technology created by the Food and Agriculture Organization (FAO) of the United Nations.

Réseau national de santé (RNS)

In the medical and health fields, the National Health Network provides connectivity to 84 hospitals, including all the 20 university hospital centers and 44 regional hospitals and 23 regional branches of the health Ministry (Directions régionales de la santé). It is managed by the Ministry's Centre informatique du ministère de la santé publique (CIMSP), providing distance information services, "télémedicine," to doctors in remote regions of the country and services to health centers far from large population areas.

Library, Information Science, and Archival Education and Training

Specialized training and education in librarianship and information sciences in Tunisia has developed very slowly, arduously, and sometimes erratically. After several years of being scattered among a few institutions it became, in the last couple of decades, centralized at one institute. Historically, formal professional training for librarians and archivists started in 1964 at the Institut Ali Bash Hamba, a public institution initially set up with

assistance from the German foundation Friedrich Naumann Stiftung several years after the country gained independence. Its main and somehow vaguely defined goal was the development and dissemination of cultural, economic, social, and technical information in Tunisia. Between 1966 and 1971 it offered training sessions lasting six months each, conducted by a corps of international instructors dispatched by the International Federation for Information and Documentation (Fédération internationale d'information et de documentation, FID). This college-level training program attracted students and professionals from French-speaking countries in Africa; about 100 of them graduated with degrees in documentation. In 1965 the Tunisian Ministry of Cultural Affairs was prompted to start a course specifically for librarians at the National Library. Although it did not last very long, the program graduated two groups of assistant librarians and four groups of library assistants at the end of four years. By the early 1970s, training of librarians was transferred to the National School of Administration (Ecole nationale d'administration, ENA). This is the school, similar to its famous French counterpart, where government officials and functionaries are trained under the jurisdiction of the Prime Ministry. The Friedrich Naumann Stiftung again provided financial support, including scholarships and recruitment of foreign lecturers. The curriculum was organized into three training cycles, each lasting two years. By 1979 library science and archival training was moved to the Institute of Journalism and Information Sciences (Institut de presse et des sciences de l'information, IPSI) under the purview of the Ministry of Higher Education, Scientific Research and Technology. It was first planned as a four-year undergraduate-level program. However, that program in turn was scrapped and replaced by another two-year professional program in library science; candidates for admission were required to take an entrance exam. A two-year graduate-level program was introduced in 1984–1985 at IPSI that accepted students with the equivalent of a bachelor's degree in any subject. Lacking in experienced faculty and relying mainly on professional librarians as part-time lecturers, that program was also cancelled a few years later despite attracting about 100 students a year. A major improvement started in the mid-1980s, when the Institut supérieur de documentation (ISD) (<http://www.isd.rnu.tn/en/default.asp>), took responsibility for developing a full-fledged undergraduate program in librarianship and archival sciences. According to its founding law,^[43] ISD is a public institution of higher education and research that provides training for managerial and professional staff in library sciences, documentation, and archives. It is part of the University of Manouba, Tunis, under the Ministry of Higher Education, Scientific Research and Technology. The ISD's original course of studies consists of a two-year training cycle for three categories of students:

- 1st category:
Beginners holding new high school finishing diploma (Baccalauréat) who plan to graduate as library assistants after a two-year program.
- 2nd category:
Graduates in other specialties planning to become librarians, documentalists, or archivists after undertaking an additional two-year training.
- 3rd category:
Holders of an undergraduate degree (four years) in other disciplines, especially humanities, who plan to be curators (conservateurs) in libraries and other resource centers.

Since 1988, ISD has offered a four-year specialized program leading to a full university degree (Maîtrise: four years). More recently it set up a graduate-level program, "Diplôme d'Etudes Supérieures Spécialisées (DESS)," roughly the equivalent of a master's degree. Admission to the program is subject to a competitive entrance examination. The Institut supérieur de documentation is currently the only university-level institution that is dedicated to providing specialized training in the field of library, information, and archival science. As of the 2006–2007 academic year, total enrollment at ISD was 1466 students: 363 in the 1st category mentioned above, 289 in the 2nd, and 814 in the 3rd; it also has 74 teaching faculty and staff. Graduates of ISD programs can apply to, and be recruited by, the National Archives, the National Library, public libraries, university libraries, resource centers and archives units (in ministries and public administrations), and private firms and companies.

Library, information science, and the archival profession

L'Association Tunisienne des bibliothécaires, documentalistes et archivistes (ATDBA), is the only professional association for librarians, archivists, and researchers in the field of information science. It was founded in 1965 and currently has 250 active members. Its main publication is RASSID: Revue de l'Association tunisienne des documentalistes, bibliothécaires et archivistes pour l'information documentaire, a multilingual journal issued four times a year.

ARCHIVES AND ARCHIVAL SCIENCE

The Superior Council of Archives, Conseil supérieur des archives, is the official governing and advisory board responsible for setting national archival policy. It is under the jurisdiction of the Prime Ministry and presided over by the prime minister. Established by virtue of Decree no. 94-1618 of 26 July 1994,^[44] the council is made up of

10 ministers and government secretaries as well as a Technical Committee charged with compiling materials to be considered and approved by the full council. The Technical Committee includes professionals and researchers in the archival field, the general director of the National Archives, representatives of the association of archivists, and archives users.

Legislation Concerning Archives and Records Keeping

- Decree no. 70-118 of April 11, 1970, concerning the reorganization of all government services under the Prime Ministry, including archives administration, which was renamed "Division des archives générales."^[45]
- Decrees no. 88-1979 and 88-1981 of December 13, 1988, concerning the general organization, structure, and management of the national archives; fixing procedures of handling and disposition of archival records.^[46]
- Decree no. 389 of February 21, 1997, containing general provisions regarding the organization and management of the National Archives that include the definition of its structure, administrative hierarchy, budget, financial arrangements, and contracts. (Decree no. 389 repeals the Decrees of December 13, 1979 and December 1988). Accordingly, public services and state bodies in Tunisia are required to elaborate, in collaboration with the National Archives, a program for the management of their records and to agree on procedures and work out methods of handling archival records throughout their lifecycle. The program should cover all functions meant to ensure proper handling of records in terms of appraisal, inventory, and classification.^[47]

The National Archives

al-Arshīf al-Waṭṭanī al-Tunīsī (Archives nationales tunisiennes, <http://www.archives.nat.tn/>)

The founding of the Tunisian National Archives (Fig. 4) dates back to 1874, when a small archival section was created within the Grand Ministry (Prime Ministry). It was initially named Centre des correspondances de l'état, or State Correspondence Center, and designated a repository of public and official records that were transferred from such locations as the royal Bardo Palace and various other document-producing sources of the civil service and state institutions. During the French colonial period (1881–1956), the Tunisian staff and administration of the center was maintained but it came under the supervision of a French senior official, *secrétaire général du gouvernement*, and its functions were restricted to internal affairs that were directly linked to the "indigenous" Tunisian population only, such as regional and local

administration, justice, religion and worship, endowments, etc. At that time, the French "resident general" (high commissioner) exclusively ran the important ministries of war and foreign affairs. In 1883 the Archives générales du gouvernement (State General Archives) was established as the repository of all official documents under the secretary general of government. Records collected by the services directly relevant to the French resident general in Tunisia were transferred to France. Since 1983, Tunisia has actively proceeded with microfilming or obtaining copies of these records. When the country became independent, the Archives générales du gouvernement took the name Archives générales. In 1967 the archives administration became known as the Division des archives générales et de la documentation (General Archives and Documentation Division). Its task was to collect and preserve the state's general archives. By 1970, it was again renamed Division des archives générales.

With a current staff of 56, including 24 professional archivists and conservation specialists, the National Archives, a financially autonomous institution that, under the oversight of the Prime Ministry, is responsible for collecting, preserving, and making accessible all archival resources, including those available abroad and deemed relevant to Tunisia. The National Archives works in close collaboration with record-producing bodies and institutions such as government ministries and public departments, institutions, and services. These bodies are required by law to develop specific methods and schedules for appraisal and management of their records. The Common records appraisal schedule, established by a prime minister in 2000 is a management tool completely integrated into the administrative processes of all government and public bodies. It fixes for each type of record the period for which it is to be preserved and made available, the period for which it is preserved as a semicurrent record, and the destination of a record or file following the expiry of its retention period, which is often disposed

Fig. 4 New building of the Tunisian National Archives.

of or transferred to the National Archives. On a local level, for regional entities such as municipalities that are outside the direct purview of the central government, the system for archival records communication and management is still in development.

The most ancient preserved record available at the National Archives dates back to 1582 A.D., although the bulk of the archives concerns mainly the period from the seventeenth century to the present and is divided into the following major groups:

- The Ottoman Period
- The Colonial Period
- Independent Tunisia
- Documentary Holdings (mostly printed monographs, periodicals, and newspapers)

The National Archives' "historical library" includes more than 6000 monographs, mainly in Arabic and French, in addition to manuscripts in Arabic, Turkish, French, Italian, and English dating back several centuries. There are also an estimated 725 periodicals and historical newspaper titles in Arabic, French, Italian, and Hebrew.

The best organized and maintained records and holdings are from the Ottoman period in Tunisia, with particularly rich holdings covering the Husaynite dynasty (1705–1881) and French colonial Tunisia, from 1881 to 1956. Most of the documents and texts concern the Tunisian state and reflect essential aspects of the political and administrative organization of the country, as well as its economic and social and cultural changes for a good part of three centuries.

Access to records is available on site at the National Archives and is strictly regulated according to type and age. "Current" official records are practically inaccessible to the general public. For noncurrent records, the periods after which public access becomes possible are according to the following categories:

- 30 years beginning with the date of the public record's creation.
- 60 years for records that:
 - Are a threat to the private life of individuals or related to national security matters
 - Contain personal information or relate to private life and behavior
 - Relate to legal matters
- 100 years for
 - Civil registers and similar official records
 - Records comprising of personal medical information and personal files

Clearance to consult records for research purposes prior to the expiration of the specified retention periods is given only if the user can provide written approval from a research institution and agrees to undergo a background

check to establish that the information wanted is not a threat to individual safety and public order.

Public access to records and use of the National Archives' reading rooms requires a small one-time fee to obtain a reader's card. Foreign nationals are allowed access provided that they display a pass approved in advance by the director of the National Archives.

Photocopying is authorized for a fee in conformity with internal Archives regulations.

Records and record groups are cataloged according to a hierarchical classification system using common characteristics such as similarity of function, subject, and type. The system, consisting of several levels of grouping, proceeds from the "general" to the "specific" and is presented in a hierarchical form with each level (class, subclass, division, and subdivision) indicated by a heading and a classification index:

- *Class:* 3000 Financial resources management
 - *Subclass:* 3100 Budget elaboration
 - *Division:* 3170 Budget change
 - *Subdivision:* 3171 Application for extra credits

Descriptors, accompanied by a classification index, are arranged alphabetically with cross-references and associated terms.

Two databases are used as the National Archives' online catalog:

- *Kitāb*
For preserved works such as monographs, documents, and periodicals in Arabic or other languages available at the National Archives. The number of records is estimated at about 10,000 with a 5–10% annual increase.
- *Dhākrah*
For records, official documents, and treaties and comprising about 75,000 entries (with a 5–10% annual increase).

ISAD (G) (General International Standard Archival Description, 2nd edition), is the standard followed for archival description in this database.

The National Archives publishes finding aids, studies, research papers, and pedagogical tools. Its official publication is "Inventaires des documents d'archives conservés."

In 2004 Tunisia established a National Archives Day, which is celebrated every February 26th "to focus attention on archives... as a key to national memory and as a source for study and research." (Fig. 5)

It is important to point out that, other than the National Archives, several local and foreign institutions hold important records relating to the modern and contemporary history of Tunisia. The most important ones are

Fig. 5 Poster celebrating Tunisia's first National Archives Day.

- The Higher Institute for the National Movement History, at Mannouba campus, holding microfilm records of the French colonial "Résidence générale."
- The Ministry of the State Property, Department of Documentation and Archives, holding historical documents of the Endowments Administration, "Jam'iyah des Habous."
- Municipalities responsible for the preservation of records relating to the civil register acts (birth, marriage, and death certificates) and those concerned with city planning.
- Courts in charge of holding and safeguarding the documents they produce.
- The Archbishopric of Tunis, holding all records relating to the Catholic population that lived in Tunis during the French colonial rule.
- The French Consulate in Tunis, holding all records relating to the civil register acts (birth, marriage, and death) of French nationals who lived in Tunisia during the Colonial Period after 1914.

Foreign-based repositories of documents that are relevant to Tunisia include notably:

- Direction des Archives du ministère des affaires étrangères (Department of the Archives of the Ministry

of Foreign Affairs), Centre Parisien 37, Quai d'Orsey, 75007, Paris, holds civil register acts of the European community in Tunisia prior to 1914 and the diplomatic correspondence of the Ministry of Foreign Affairs.

- Archives nationales, in Paris, previously named Centre historique des archives nationales de France.
- Centre des archives d'outre-mer, Aix-en-Provence, France.
- The diplomatic archives of several countries, namely, England, Italy, Germany, United States, Sweden, and Norway, have records relating to the history of modern Tunisia.

Archival education and the profession

Training and education for archivist at the university level is at the Institute of Information Science (ISD), described in a previous section. The main professional association is also the Tunisian Association of Documentalists, Librarians, and Archivists (ATDBA), established in the mid-1960s.

Finally, it should be mentioned that in 2005 the International Association of Francophone Archives launched its International Francophone Archival Portal (PIAF) (<http://www.piaf-archives.org>) as a clearinghouse offering training for archivists of the Francophone community. International Francophone Archival Portal offers free online basic training on records and archives management focusing on the continuing education needs of archival technicians and professionals, but it does not result in a diploma.

MUSEUMS AND MUSEOLOGY

General Background

There are two leading bodies in the area of museology, historic preservation, and cultural heritage in Tunisia:

1. The Agency for Heritage Development and Cultural Promotion, Agence de mise en valeur du patrimoine et de promotion culturelle (AMVPPC) (<http://www.igm.com.tn/amvppc/eng/accueil.php>), is a national agency established in 1988 under the authority of the Ministry of Culture and Heritage Conservation to restore and manage the country's historical and archeological heritage.^[48] Its mission is to implement government policy in various fields related to the restoration, preservation, management, and promotion of the country's archaeological and historical heritage at about 60 sites, monuments, and museums. It is the body in charge of delivering authorization required for any activities taking place within the confines of sites under its responsibility. Agence de mise en valeur du patrimoine et de promotion culturelle is headed by a director general and has seven departments: Technical, Cultural Promotion, Management, Production and

Organization, Study and Programming, Administration and Finance, and Coordination and Follow-Up. The agency undertook the rehabilitation of older museums such as the National Bardo Museum, and the museums of Enfidha, Nabeul, and El Jem, as well as the Popular Arts and Traditions museums of Monastir and Houmt-Souk. It created new museums as well in Moknine, Chemtou, and Mahdia and the Sahara museum in Douz and also participated in the creation and design of museums for other parties: the National Military Museum (Qasr al-Wardah), the Mareth Line Museum, the National Guard Museum, and the Film Museum. As a promoter of cultural tourism, it played a central role in the creation of the Carthage-Sidi Bou Said Archaeological Park; the refurbishment of the Baron d'Erlanger's palace in Sidi Bou Said, housing the Center of Arab and Mediterranean Music; the Archaeological Park of Dougga; and the Sbeitla-Kasserine Archaeological Park. In 2002, in an effort to modernize the country's cultural infrastructure, the Tunisian government launched, with support from the World Bank, a multiyear project that would improve the sector through strengthening the legal and institutional framework, encouraging cultural tourism, and refurbishing six selected sites: Ancient Carthage, Bardo Museum, Sousse Museum, the Medina Old City of Qayrawan, the archaeological site of Oudna, and the island of Jerbah. A unit operating within the AMVPPC is responsible for the project's implementation.

2. The National Institute for Cultural Heritage, Institut national du patrimoine (INP) (<http://www.inp.rnrt.tn/>), was founded in 1957 as the Institut national d'archéologie et d'art, before changing its name in 1993. It is a technical and scientific institution under the Ministry of Culture in charge of preserving, studying, and making the cultural, archeological, historic, and artistic heritage of the country accessible to the public. The institute has various technical facilities, such as a central laboratory, a center for the restoration of Qayrawan manuscripts (Centre de restauration des manuscrits de Kairouan), a center for calligraphy (Centre national de la calligraphie), and an education center (Cours de Tunis) for training Tunisian and North African architects in different conservation specialties. Its publications include

- Africa: journal for research and excavations in prehistoric and Islamic antiquities in Tunisia, 1966–
- Reppal: research journal for Phoenician, Punic, and Lybico-Berber antiquities
- La Revue des arts des traditions populaires, specializing in folklore and popular cultural monuments, objects, traditions, rituals, and beliefs
- Bulletin du CEDAC: annual information letter published by the Centre d'études et de documentation archéologique de Carthage, an affiliate

institution of INP, reporting on archeological digs and excavation results at the Carthage site.

Tunisia's cultural assets include many archaeological sites, parks, and historical settlements, several of which are listed as World Heritage Sites under the international convention administered by UNESCO. There are numerous museums located throughout the country, varying widely in significance from the national and prestigious to the smaller and pedestrian. Among the 18 historical and archaeological sites in Tunisia that receive visitors and the 27 museums, "antiquariums," and archaeological, historical, and natural parks, the following are particularly noteworthy.

Museums

Musée national du Bardo (<http://www.di.com.tn/museebardo/>)

The Bardo National Museum (Fig. 6) houses the largest—and arguably the finest—collection of Roman mosaics in the world. Situated in Bardo, a near suburb of Tunis, the museum building was originally a residence/palace that had been restored and expanded over the centuries before being dedicated first in 1882 as a museum, namely, al-Mathāʾaf al-ʿAlawī: Le Musée Alaoui. In 1899 a second extension space, called the small palace, was added to it to house collections of Islamic arts and artifacts. In 1956, at Tunisia's independence, it officially became the National Museum in Bardo.

Bardo Museum is spread over approximately 11,000 m². The exhibits represent vast collections of relics from every period of Tunisia's past, and collections are presented by department-era: Prehistory, Punic, Roman, Christian, Arab-Moslem, Bronze and Greek marbles, etc. Many of

Fig. 6 Bardo National Museum main entrance, on the right, as seen in the summer of 2007 prior to renovation work.

the exhibits are impressive from an archaeological point of view, as well as compelling and beautiful, although the premises, the labyrinthine ground plan, and exhibition rooms have been in need of renovation for many years. Work on the renovation and alteration of the building has been contracted to the French architectural agency Codou Hindley and is expected to last 27 months. It will enlarge the museum by doubling the existing space. The planned modernization will add new, handicapped-accessible structures and underground spaces for public displays in addition to an auditorium, a laboratory, a cafeteria, and a restaurant.

Musée national de Carthage

Carthage National Museum, also known as the National Archeological Museum, is located on the hill of Byrsa in close proximity to the ancient city of Carthage and to several important excavation sites. Officially founded in 1964, it is a repository of numerous antiquities and the product of archaeological excavations since the nineteenth century. It has a great mosaics collection and other archeological materials. Exhibits include information about the course of the different excavation campaigns, a small scale model of Punic Carthage, the Capitol built by the Romans on the ruins of Punic Carthage, tophets used for child sacrifice, Punic and early Christian antiquities, mosaics, jewelry and ornaments, everyday objects, clay masks, funerary stelae and sarcophagi, etc. The two-story museum itself is relatively small but is incorporated into an area of another seven sites, or the museum gardens, where a variety of ancient remains are on display, including a 10 f high marble statue commemorating Louis IX's crusade to Tunis (1270)—though the statue is in fact a likeness of Emperor Charles V. The museum is the official center for all research activities, preservation, and administration of the Carthage site, where the Centre d'études et de documentation archeologique de Carthage is located (see Bulletin du CEDAC). It is therefore a first stop immediately before exploring the ruins of Carthage itself, a UNESCO World Heritage site.

Musée national d'Utique (<http://www.inp.rnrt.tn/Museeutique.htm>)

Commonly known as the first colony founded by the Phoenicians in North Africa, Utica was originally founded around the eighth century B.C. as a port north of Carthage on the trade route of the Phoenicians to the western Mediterranean. Excavations at the site have yielded two Punic cemeteries and Roman ruins, including baths and a villa with mosaics. The two-room museum is located on the site and contains Punic and area exhibits going back to the seventh century B.C.

Musée archéologique de Chintou (<http://www.chintou.com/>)

The museum and ancient site at Chintou, the country's site museum, is an archeological complex of 10,000 m² developed under the authority of the Tunisian Institute of National Heritage with assistance from the German Archaeological Institute in Rome.

The museum contains four exhibit rooms in three wings—more than 16,145 ft² displaying the results of over 25 years of excavations at the ancient quarries and the site of Chintou. Chintou's famous golden marble was first quarried under the Numidians (149–118 B.C.). Under Roman rule, the marble served as decoration in public buildings all over the empire, including in Rome. The site offers a number of finds from various historic eras, including pagan temples, Numidian tombs, the remnants of a fifth century Christian church, a Roman way, marble quarries, and a turbine-driven grain mill. At the beginning of the twentieth century the marble yard was restored to working condition. The museum itself houses, in addition to an information space and lecture theatre, an exceptional treasure of 1647 gold coins and stresses the Numidian civilization and the extraction of marble by the Romans. The exhibits are arranged by topic:

- Protohistoric Simitthu 500–100 B.C.
- The Royal Numidian Altar
- Marmor Numidicum
- The Ancient Marble of Simitthus
- Roman Town Colonia Iulia Augusta Numidica Simitthensium
- Funeral Monuments

Musée des arts islamiques de Rakkada

The Raqqada Museum, created in 1986 and housed in a former presidential palace near the city of Qayrawan, has the country's largest collection of Islamic art, in particular, manuscripts of the Koran from the Great Mosque of Qayrawan, famously called the Blue Koran. It also has an interesting collection of ceramics, glass, and bronze objects and numerous coins from various medieval periods.

Musée de Sidi Kasim al-Jalizi (Ceramic Museum)

Located in the mausoleum of Sīdī Qāsim al-Jalīzī, a famous saint and ceramist of Andalusian origin, in the western part of the old city in Tunis. It is a small museum featuring old ceramics. The fifteenth century mausoleum is an homage to this saint, whose history reports that he was a manufacturer of ceramic squares, hence its name (ceramic squares in the North African dialect are called *jalīzi* or *zalīz*). Since 1981 this restored building has sheltered an old ceramics collection

(thirteenth to sixteenth centuries) and an epigraphic collection of old funerary steles.

Musée des arts et traditions populaires

The Museum of Popular Art and Tradition, also known as Musée Dar Ben Abdallah and as Musée du patrimoine traditionnel de la ville de Tunis, was inaugurated in 1978 and housed in an eighteenth century bourgeois residence in the center of the Medina (old city) of Tunis. It has two sections, one for family life, customs, and rites and the other for public life in the city. On display are various collections of traditional Tunisian domestic objects, costumes, jewelry, and old furniture. There is a display room reserved for the horse and the rider and their gear and ornaments.

Musée Dar Cherait (<http://www.darcherait.com.tn/>)

This is the first private and possibly the best “living museum” in the country. Founded in 1990 in Tozeur, a southern desert oasis town that for centuries served as a caravan station, it contains art objects depicting the life-style in bygone times of a well-to-do middle-class Tunisian family, complete with reconstructed rooms, scenes of daily life, and samples of pottery, utensils, and antiques. There are also replicas of the bedroom of the last *bey* (Tunisia’s monarch), a palace scene, and a Bedouin tent. The private collection contains good examples of centuries-old Tunisian artifacts. The museum building, part of the Dar Cherait Complex, is housed in a restored mansion and a Bedouin tent.

Musée Sidi Zitouni

This popular art and traditions museum was set up in 1968 in the shrine of the saint Sīdī Zitounī, located in Hāawmat al-Suq, on the southern island of Jerbah. Its unique collections depict traditional daily life in several adjacent towns and villages and include formal Jewish and Moslem clothing as well as samples of silver jewelry that was the specialty of local Jewish artisans; a reconstruction of a pottery workshop; and a display of utensils, pottery, and old furniture.

Additionally, there are other important historical and archeological museums throughout the country that should be mentioned: Musée du site de Bulla Regia, Musée du site de Makthar, Musée archéologique d’Enfidha, Musée archéologique de Sousse, Musée archéologique de Nabeul, Musée du site de Kerkouane, Musée archéologique de Sbeitla, Musée archéologique de Chintou, Musée archéologique de Lamta, Musée archéologique de Salakta, Musée archéologique d’El Jem, Musée archéologique de Gafsa, and Musée archéologique de Sfax.

The World Heritage Committee has inscribed on its World Heritage List for cultural values the following Tunisian Cultural Properties: amphitheater of El Jem, in 1979; site of the ancient city of Carthage, in 1979; the Medina (old city) of Tunis, in 1979; Punic town of Kerkouane and its necropolis, in 1985; Medina of Sousse, in 1988; the old city of Kairouan, in 1988; Dougga/Thugga archeological site, in 1997; and the nature preserve Ichkeul National Park, in 1980.

Education and the profession in museology

Training and education in archaeology, museology, ethnography, protection, and evaluation of the national heritage is done mostly within the INP. For many decades curators and cadres in the field have also been graduates of L’école du Louvre à Paris en muséologie in France. The country’s quasi-professional association is the Comité national des musées, founded in 1961 and currently headquartered at the Bardo Museum.

National Parks

Natural parks and sites

Ichkeul National Park. Of Tunisia’s six national parks, the most significant is the one around the lake, Ichkeul, in the north. Officially designated as a Wetland World Heritage Site, it is one of only two water-based, UNESCO-protected biosphere reserves in the world—the other is the Florida Everglades. It is the best vantage point from which to watch Tunisia’s most colorful birds. As a bird sanctuary, the park is best visited between October and February, when it becomes a hugely populated stopping point for waterfowl and game birds migrating between Africa and Europe. Among other animal species there are water buffalo, wild boar, jackals, mongoose, and European genets as well as a limited number of crested porcupines. Djebel Ichkeul (Ichkeul massif) was originally acquired by the state in 1891; until that date the lake surrounding Djebel Ichkeul had been used as a hunting reserve. The creation of the national park was ratified by Presidential Decree No. 80-1608, of December 18, 1980.^[49]

Belvédère Park and zoological gardens

Established in 1892 on a hill near the center of Tunis, Belvédère was designed by Joseph Lafacade, chief gardener of the city of Paris, France, and first opened to the public in 1910. Today the park is the largest urban park in the country, covering 110 ha. At its center is a sixteenth century Qubbah, a pavilion that provides an excellent view of the city and an example of neo-Moorish-inspired Tunisian architecture. Beside the park there is a zoo, Parc Zoologique de la Ville de Tunis, featuring African fauna, including 61 mammal, 94 bird, and 5 reptile species.

It was set up in 1963 with German assistance and covers 15 hectares.

Musée océanographique de Salammbô “Dar el Hout” (<http://www.mes.tn/instm/fr/infrastructure/musee.html>)

The national maritime and oceanography museum was built in 1924 during the French era in Tunisia in Salambo, not far from ancient Carthage, on a site called Palais des Suffètes de la Mer. Today, after a number of restructuring improvements, the museum has, in addition to a laboratory, a library, and a conference room, eleven display rooms, or “salles,” that include aquariums:

- Salle 1: La Tunisie pays marin
- Salle 2: La Tunisie et la Méditerranée
- Salle 3: Les aquariums d’eau douce
- Salle 4: Les lagunes Tunisiennes
- Salle 5: Migration de l’anguille
- Salle 6: Les îles et les espèces protégées
- Salle 7: Le littoral
- Salle 8: La communauté d’oiseaux
- Salle 9: Les techniques de pêche
- Salle 10: Les poissons
- Salle 11: Les aquariums d’eau de mer

Cultural and Arts Centers

Maison des arts “Dar el founoun”

As the preeminent national center for cultural and musical activities and art exhibitions affiliated with the Ministry of Culture, the center’s original mission was to encourage and showcase plastic arts by Tunisian and foreign painters. Its activities revolve mainly around free exhibitions and occasional conferences. It has a 6000-volumes library and publishes monographs, catalogs, and brochures on a small scale. The site is close to the Belvédère garden in Tunis and existed as a cultural center long before it gained its new name and vocation in 1992.

Centre d’arts vivants de la ville de Radès

In 1982, the Ministry of Culture created the center as an education and training academy for student artists and professionals in the arts field. In addition to courses, it organizes exhibitions, conferences, and workshops for new and established artists. It also functions as a fine arts academy, accepting applications for artist-in-residence positions that last three to six months. It is open to the public and periodically organizes special workshop sessions for youth.

Centre culturel international d’Hammamet

Located in a villa built in 1927 in the north-eastern resort town of Hammamet by a wealthy Romanian named

George Sebastian, the International Cultural Center was founded in 1962. It includes an open arena and theater stage built in 1964 based on Greek and Roman models. It is the setting of an international festival of music and drama that takes place in July and August each year. Described by Frank Lloyd Wright as the most beautiful villa in the world, Sebastian’s house and surrounding gardens with over 300 species of plants was a destination of prominent personalities such as Winston Churchill, Anthony Eden, and Field Marshall Erwin Rommel and a variety of artists who came to visit and create. It continues to function as an international artists’ retreat.

CONCLUSION

Since the country gained independence, successive Tunisian governments have pursued reformist and modernist policies, especially in the cultural and educational spheres. While well aware of its millennia-old cultural roots and being custodian of vestiges that are considered important World Heritage sites, this emerging country faces a number of challenges. In spite of Tunisia’s economic and social successes, its cultural scene is still in need of realizing full potential. The state remains the dominating sponsor and patron of culture and the arts. In this respect, it has succeeded in developing a considerable cultural infrastructure throughout the country. It has also built an adequate statutory framework consisting of legislation related to cultural matters that is designed to ensure, for instance, the protection of intellectual and artistic property, the preservation of the country’s heritage, and guaranteed freedom of information and the media. In reality, however, the country still faces a long road ahead with regard to all of these issues. Moreover, despite concerted efforts over the decades since independence, there is a manifest lack of interest in books and reading among a large swath of the population, and publishing levels outside official and educational institutions continue to be low. Critics also see serious shortcomings in the areas of artistic creation and theatrical and cinematographic productions. Tunisia’s rich cultural heritage and assets are underappreciated, and the various concerted measures undertaken by the government authorities in recent years to encourage, for instance, cultural tourism were mainly geared toward foreign visitors. There is arguably looming danger to many historical sites as a consequence of the conflicting pressures on land use from urban, agricultural, and tourism expansion. Some historical sites are deteriorating due to aging and weathering or inadequate maintenance. Finally, it must be pointed out that in the area of information and communication technologies, the Tunisian government has invested heavily in online services, computer training, and hardware acquisition so much that the World Economic Forum recently designated the country as first in Africa for network readiness.

Ukraine: Libraries

Lyudmila Shpilevaya

New York Public Library, New York, New York, U.S.A.

Abstract

The geopolitical location of Ukraine in Central-Eastern Europe has significantly influenced the historical and present development of the country and its libraries. The Ukraine became a fully sovereign state in 1991, after long periods of successive domination by Poland-Lithuania, Russia, and the Soviet Union. Since Ukraine became independent libraries have been rethinking their role in society, considering different goals and facing new challenges. Those challenges are closely linked to democratic changes occurring in Ukraine during the last decade. This entry gives a brief history of libraries in Ukraine, reviews conditions and development of Ukrainian libraries, and discusses new trends in their activities. It also contains basic information about some of the major libraries in Ukraine.

INTRODUCTION

Ukraine is located in Central-Eastern Europe (see Fig. 1). The geopolitical location of Ukraine has significantly influenced the historical and present development of the country. Ukraine is the second largest country in Europe. The Ukrainian culture and dramatic history goes back to the 5th century, when Kyiv (the capital of Ukraine) was founded. The Ukrainian Parliament passed a declaration of sovereignty in July 1990 and, in August 1991, declared Ukraine independent of the Union of Soviet Socialist Republics (USSR).

Libraries and librarianship in Ukraine reflect the history and development of the country and its people. Because Ukraine became an independent sovereign state, the libraries have been rethinking their role in society, considering different goals and facing new challenges. Those challenges are closely linked to democratic changes occurring in Ukraine during the last decade. This entry gives a brief history of libraries in Ukraine, reviews conditions and development of Ukrainian libraries, and discusses new trends in their activities. It also contains basic information about some of the major libraries in Ukraine.

HISTORY OF LIBRARIES IN UKRAINE

Earliest chronicles of libraries in Ukraine date from the 11th century (the Library of Saint Sophia's Cathedral, also known as "The Prince of Kyiv Rus Yaroslav's the Wise Library" and "The Library of the Kyiv-Pechers'ka Lavra").^[1] "At the beginning of the 14th century a large collection (215 manuscripts and books) was housed at Supral' Monastery; there were smaller ones at Sluc'k (founded 1494), L'viv (founded 1579), and elsewhere."^[2] There were well-known libraries located in monasteries

and private libraries owned by famous clergymen and Cossack's nobility during the 16th–18th centuries. Examples of these are the libraries of L'viv Stavropygian Brotherhood (16th century); Petro Mohyla (1596–1647), later donated to the Kyiv Academy; Dmytro Tuptalo; Feofan Prokopovych (1681–1736), containing 3000 volumes; and Lazar Baranovych.^[2]

During the 19th century, many academic and public libraries were founded. Some of them are the libraries in Kharkiv (1805), Odesa (1829), and the Library of Kyiv University (1834).^[3]

There was a short period when Ukraine attempted to establish itself as an independent state (1918–1921). At that time, the National Library of the Ukrainian State was established (1918). However, Ukraine lost its own state system and became a part of the USSR in 1922. During the World War II, German troops occupied Ukrainian territory (1941–1944). This war brought great losses to the libraries. Before the beginning of the Second World War, there were 44,662 libraries with total book collections amounting to 102 million items.^[1] The official estimates of losses say that more than 40,000 libraries were ruined or damaged and about 80 million books were destroyed or stolen. Nevertheless, the library network in Ukraine was basically restored by 1950.^[1] Under the Soviet regime, the libraries had a strict centralized administration ensuring strong censorship and dictating communist ideology. The Soviet Union had proclaimed a new "nationality," "the Soviet human being," which meant the erasure of individual national and ethnic identities. The libraries were an important instrument toward the achievement of that goal. The libraries of the Soviet republics were deprived of their individual identities. They were all headed by the Moscow library administration, and they served Moscow politics and ideologies.

Fig. 1 Map of Ukraine.

CONTEMPORARY LIBRARY SYSTEM IN UKRAINE

Most of the modern library network in Ukraine had been formed during the Soviet era (1920–1991). Since 1991, when Ukraine achieved its desired independence and became a sovereign state, the libraries have been rethinking their role in the society, considering different goals and facing new challenges. The library community is currently working toward “new library policies in Ukraine based on free access to ideas, library materials and services. Intellectual freedom issues are the basis of contemporary library and information policies in Ukraine.”^[4] Intellectual freedom is closely connected to important issues such as open and free access to information and resistance to censorship. Successful achievement of these goals is highly contingent on changes in the librarians’ attitudes and training.

The information technologies that have changed the missions, goals, and functions of world libraries during the last 10 years have become a part of library practice in Ukraine. Users of the Internet in Ukraine in 1999 have increased 3 times (from 0.5 million at the beginning of the year to 1.5 million at the end), and the user growth rate was the highest among all the European countries.^[5] The impact of computerization has significantly changed the tradition functions of library services. Now Ukrainian librarians, along with their traditional services, are providing virtual services such as e-mailed reference, electronic catalogs, and Internet access. Most librarians welcome technological changes but also see the value in their historical function of assisting people to find information—whether digitized or between the covers of a book. They understand that for success, the professional librarian needs a combination of communication and computer skills. When the computerization of libraries is

successfully completed and a general unified network is created, the new information technologies will ease the tasks related to bibliographic and authority control.

Another important task for libraries is the creation of a national bibliography “Ukrainica,” which will accumulate all publications published in Ukraine, all publications in Ukrainian language, irrespective of place of publication, and all publications linked to Ukraine irrespective of language. Three libraries, the Vernadsky National Library, the National Parliament Library, and the Stefanyk Lviv Scientific Library, are at the head of this undertaking. The Vernadsky National Library has already published the fifth volume of the “National Bibliography of Ukraine.”

The decade has not been easy for the Ukrainian people as they strive to create a democratic state, a free-market economy, and a civil society. This transition period has been extremely difficult for libraries and librarians who now have far less financial support from the government than during the Soviet period.^[6]

In recent years, there has been positive movement in the state library politics. Important documents such as “The Law of Ukraine on Libraries and Librarianship” (1995), “The Program on the Preservation of Library and Archival Collections, 2000–2005” (approved by the Cabinet of Ministries of Ukraine, 1999), “The Program of Libraries’ Acquisitions for the Period up to 2005” (approved by the Cabinet of Ministries of Ukraine, 2002), and two Presidential Decrees, “Establishment of the All-Ukrainian Day of Librarians—September, 30th” (1998) and “Urgent Measures toward Development of Libraries of Ukraine” (2000), have been signed.^[7] Those documents increase the prestige of the libraries and give them new parameters for improved and increased operations. Although Ukraine has affirmed these documents, they

have not been followed by either sufficient funding or support to meet the libraries' growth and development needs.

Ukrainian libraries are striving to integrate into the international library society. They are working on extending their international contacts, seeking international partnerships and funding, and participating in international associations and programs. One of the results of such partnerships is the bilingual (Ukrainian/English) Internet reference site, "Ukrainian Library World Gateway."^[8] This Web-based directory has been developed by the British Council in Ukraine, the Ukrainian Library Association, and the Library of the National University "Kyiv-Mohyla Academy." It is a centralized source of information regarding to Ukrainian libraries and professional information for Ukrainian librarians.

The present library network of Ukraine consists of public, academic, school, university, and special libraries (Fig. 2). The greatest problems facing Ukrainian libraries of all types are insufficient budgets for collections and general operating expenses, substandard salaries for librarians, and low levels of computerization and Internet access for both library professionals and users.

Ukrainian librarians have two professional associations: The Association of Ukrainian Libraries (ABU) and The Ukrainian Library Association (UBA). Membership in both associations is open to individual librarians as well as for the libraries. The Association of Ukrainian Libraries (ABU), founded in 1991, unites mostly academic, medical, agricultural, technical, and some university libraries. Information on this organization can be founded on its Web site.^[9] The Ukrainian Library Association (UBA) was founded in 1995. The Web site for this organization provides practical information for professionals in the field.^[10]

There are two levels of professional library education: "medium" that is the equivalent of 2-year college program and "high" level of professional education that requires completion of a 4-year program at an accredited college or university. Three academic institutions in Ukraine

currently certify the librarians with "high" qualification: The Kyiv National University of Culture and Arts,^[11] The Kharkiv State Academy of Culture,^[12] and The Rivne State Institute of Culture.

Public Libraries

Public libraries are the most extended library system under the patronage of the Ministry of Culture and Arts of Ukraine. According to the Ministry statistics, there are almost 20,000 public libraries in Ukraine. The complete book collections of them amount to 302 million issues. On average, a public library contains 16,000 publications; a village library contains 10,000. The book supply, per capita, is about 6 issues in municipal libraries and 10 issues per capita in village libraries. These numbers are relatively high in comparison to the IFLA standards, which recommend sustaining collections based on a count of three books per capita in small towns and villages and two books per capita in more populated areas. The book supply in Ukrainian village libraries is three times larger than world standards. It is estimated that there are 17 million users of the public libraries in Ukraine. However, the amount of new acquisitions in recent years is three times less than the International Federation of Library Associations and Institutions (IFLA) standard, 70 publications per 1000 people.^[13] Compared to other types of libraries, the public libraries are funded better, their collections are more or less updated, and more and more regional libraries are opening their own Web sites. An important role in solving the problem of public libraries' computerizations belongs to the Library Electronic Access Project (LEAP). This is a project of the Public Affairs Section of the U.S. Embassy. It helps to create free Internet centers in public libraries and to provide an open exchange of information and communication. Public libraries have received grants up to \$24,000 for computer equipment, software, Internet access, and training. In the last 2 years, 71 Internet centers have been opened in public libraries throughout Ukraine.^[14]

The National Parliamentary Library of Ukraine

Founded in 1866, as a public library, this library became the State Library of Ukraine in 1957. In 1994, the status of national library was conferred and it was renamed "The National Parliamentary Library of Ukraine" (NPLU). This library is the main library of the Ministry of Culture and Arts of Ukraine, and it is the central library of the Ukrainian public library system. The NPLU is a research institution in library science and bibliography. It serves as a national depository for all Ukrainian publications and is a center for international book exchange. Its collection is universal in character and amounts to more than 4 million issues, including rare Old-Slavonic books of the 16th–18th centuries.^[15] NPLU considers formation of an electronic

Type of Libraries	Amount of libraries	Amount of collection (million)	Amount of readers (million)	Use of library materials (million)	Amount of library staff (thousand)
Public	20,000	350	17	350	36
Libraries of educational institutions, including schools	20,800	8	1,6	10	18,7
University libraries	267	106	1,5	102	6,5
Technical/Industry	2,500	156	0,75	10	3,5
Medical	1,033	30	0,77	25,3	2,2
Agricultural	275	21	3	20	2
Academic	96	29	0,37	8	1
Total	45,000	700	25	500	70

Fig. 2 Libraries in Ukraine statistics.

database, including the establishment of electronic catalogs linking them to other library and research institutions around the world, as its primary goal. At present, the library has established an electronic catalog of new acquisitions (containing more than 209,000 bibliographic records) and an electronic catalog of articles from Ukrainian and Russian research publications (more than 200,000 bibliographic records). The creation of the information system and expanded access to world information resources is growing through grants and aid from international charitable foundations and International Research & Exchanges Board (IREX).^[16]

Korolenko State Scientific Library in Kharkiv

One of the oldest and largest libraries in Ukraine was founded in 1886 as a public library. A significant role in the development of the library was played by notable figures in Ukrainian history and culture; among them are professors Bahalii and Sumtsov and librarian Khavkina. At the beginning of the 20th century, many foreign libraries contributed to the development of the unique collection of the library, including The New York Public Library, The Library of Congress, and The National Library of France.^[3] In 1921, the library acquired the designation of state library and became a national depository. The collections of the library run to more than 6 million items, including 50,000 in the rare book collection, more than 600,000 Ukrainian language publications, and a unique collection of musical scores (104,000 items). Like other Ukrainian libraries, this one is working toward the automation and computerization of library processes. The library is also a research center in the field of library science. Each year, it publishes approximately 30 titles of bibliographies and books on librarianship.^[15]

The State Library of Ukraine for Children

Founded in 1967, it is the primary children's library in Ukraine and the national depository of children's literature. It is also the research, reference-bibliographic, and consulting center for more than 1000 children's libraries and about 22,000 school libraries in Ukraine. Its collections run to 440,000 books, magazines, audio recordings, videos, and CDs. Each year, about 18,000 users visit the library. The library hosts many different activities and events for children at the library. Examples include a puppet theater, theater studio "Ovation" and a club of connoisseurs of Ukrainian arts, and circles of soft toys "Fantastic Needle." The library publishes the bibliographies of recommended reading for different age groups (also available online), some topical bibliographies, and method materials for teachers and children's librarians. The library Web site and online catalog are also available.^[17]

Academic Libraries

The network of academic libraries in Ukraine consists of The Vernadsky National Library, The Stefanyk Library of the National Academy of Sciences of Ukraine, and 96 other libraries of the scientific-research institutions of the National Academy of Sciences of Ukraine. The complete academic library network's collections amount to 26 million items of materials, including about 6 million in foreign languages. These collections serve as a document base for scientific research and experiments in different areas of humanities, social sciences, engineering and technology, business, sciences, and arts. Annually, the academic libraries of Ukraine serve more than 208,000 users.^[18]

The Vernadsky National Library of Ukraine

The Vernadsky National Library of Ukraine is the largest library in Ukraine. Founded in 1918, as the National Library of the Ukrainian State, it changed its functions several times as well as its name. In 1996, the library received the status of the National Library and its contemporary name and designation. The library contains many distinctive collections that are universal in scope and range from the 3rd century BC to contemporary foreign and Ukrainian publications. A fire in May 1964 inflicted significant damage on the collections of the library.^[19] In October 2002, more than 200,000 books, magazines, and newspapers were heavily damaged by water, steam, and humidity when a pipeline in the library's central heating system began leaking.^[20]

There are more than 14 million items in the library holdings. Annually, the library receives 140,000–160,000 documents (books, magazines, newspapers, etc.). Each year, about 250,000 readers use the library resources and receive 3.5 to 4 million documents.^[21] Since 1969, the library has developed a large collection of publications of the United Nations (UN) and its specialized bodies. Every year, it receives more than 15,000 UN documents. The library maintains an international book exchange with more than 1400 academic foreign institutes and libraries participating. There are more than 30 catalogs and card files and a specialized collection of 160,000 reference and bibliographical publications, including one of the few sets in Eastern Europe of the printed catalog of the New York Public Library in 800 volumes.^[19] The Vernadsky National Library has more than 250 computers in use for creating the National Electronic Library of Ukraine and to serve readers by providing electronic information resources. The library has about 40 departments, staffed by 900 employees.^[21]

The Lviv Stefanyk Scientific Library

The Stefanyk Library of the National Academy of Sciences of Ukraine is one of the largest libraries of Ukraine.

It was founded in 1940, based on the collections of several private and institutional libraries, including the libraries of the Ossolineum, The Shevchenko Scientific Society, and The Lviv National Home. In 1989, the library acquired the status of an official research institute. The sole Research Center of Periodicals in Ukraine functions in this library. The Lviv Stefanyk Scientific Library's research priorities include the following: "Documental Memory" of Ukraine, bibliography and librarianship, and rare books collection. The library personnel numbers about 300 employees. The library collections have more than 7 million items, including the remarkable collection of Ukrainian periodicals of the 19th–20th centuries, rare books (250,000 items), and manuscript holdings of more than 120,000 units from the 13th to 20th centuries. These collections make The Lviv Stefanyk Scientific Library the second richest library in Ukraine.^[22]

The University Libraries

The Maksymovych Scientific Library of the National Shevchenko University

The library was founded in 1834, at the same time as the university. Its collection was based on the library of the Kremenets Lyceum holdings. Now the library collection counts more than 3.5 million items including more than 16,000 titles of periodicals. Among these are rare books of the 15th–19th centuries in Old-Slavonic, Ukrainian, Russian, Polish, German, French, Italian, and English, the works by University professors from 1837 until present, and books (with autographs) of famous figures in the fields of science and arts. Annually, more than 72,000 readers are served in 32 reading rooms and 13 circulation divisions. The library provides different activities such as authors' readings, literature debates, and book exhibitions. The library is a research center that coordinates and consults with more than 150 other university and college libraries in Ukraine.^[15]

Scientific Library of the National University "Kyiv-Mohyla Academy"

This library is one of the newest research libraries in Ukraine. It is an important part of the university education and creative laboratory. This library began in 1992, with one book and two librarians. Ten years later, at the beginning of 2002, its collections consisted of 300,000 volumes/80,000 titles. The library provides services for students and professors based on its own collections and database as well as utilizing the resources of other Ukrainian libraries. The library introduced methods such as barcoding in circulation and checkpoint monitoring systems. This library is one of the very few libraries that uses international standards such as Anglo-American cataloging rules (AACR-2), U.S. machine readable cataloging

(USMARC) format for bibliographic and authority data, and the Library of Congress Subject Headings. The library has received financial support and grants from International Renaissance Foundation (IRF), the America House, International Research & Exchanges Board (IREX), the German Library Institute, Lange & Springer, McArthur Foundation, and others. The library has an electronic catalog and database.^[23]

Special Libraries

Special libraries include a wide range of libraries that belong to different businesses and organizations. They incorporate medical, technical, and agricultural libraries as well as libraries of different ministries and governmental organizations. The libraries for the blind also belong in this category.

The State Scientific Medical Library of Ukraine

The State Scientific Medical Library of the Healthcare Ministry of Ukraine, founded in 1930, is one of the largest medical libraries in Europe. It is a research, consulting, and administrative center for 998 medical libraries in Ukraine. It is also a national depository of publications on medicine and related fields. Its complete book collection amounts to 1.3 million items, dating from the 16th century to current editions.^[15] The library also maintains the largest department of patents and normative technical documentations in medicine in the country. The library has official exchange partners in 32 countries that allow improvement and development of the library collection. There are a few card catalogs, including alphabetical, systematical/topical, and subject catalogs. Since 1993, the library has generated electronic catalog of books and dissertations, and since 1998—electronic catalog of articles. The library Web site (only in Ukrainian) gives information about the library, its facilities, reference sources, and links to other medical libraries.^[24]

Agricultural Libraries

In the category of special libraries, the agricultural libraries play a very important role in agrarian Ukraine. The network of agricultural libraries consists of 273 libraries, including 20 libraries of agricultural universities, 77 libraries of agricultural research institutes and their branches, 61 libraries of research-experimental stations, and 115 libraries of agricultural colleges. They have concentrated about 20 million of items of general and specific information resources of agriculture and related fields. Annually, more than 700,000 users visit the agricultural libraries and borrow 19 million documents, including books, magazines, newspapers, and patents.^[25]

The Scientific Agricultural Library of the National Agricultural University

Founded in 1921, the library is the main research, consulting, and interlibrary loan center of the agricultural libraries network. It is also the national depository of agricultural publications. The library collection runs to more than 1 million books, magazines, and dissertations in Ukrainian, Russian, and other languages. Annually, the library receives more than 30,000 books and 600 periodical titles, including foreign publications.^[15] The special collection of rare books includes the works by famous agricultural scientists Dokuchaev, Vavilov, Chaianov, and Williams. The library contains valuable Russian periodicals of the 19th century, e.g., “Trudy Volnogo Ekonomicheskogo Obshchestva” and “Selskii khoziai” (1888–1917). The library has Yearbooks of the Department of Agriculture of the United States dating from 1896.^[3] The library activities are not limited to collection development and public service. They include research and consultation services on the specifics of agriculture libraries, and they provide continuing education for agricultural network librarians. The library also publishes information relevant to both the fields of agriculture and agriculture librarianship. The library has developed and begun to create an “Electronic Agricultural Library.” They organize seminars, workshops, and conferences for librarians. On the pages of the Library’s Bulletin (first published in 2001), readers can find reviews of the practices of agricultural libraries and exchange information and experiences in that field.^[25] Besides the bulletin, the library publishes monthly lists of new agricultural publications and some topical bibliographies.

The State Scientific Technical Library of Ukraine

Founded in 1935, the library is the primary and the largest technical library in Ukraine. It is a national depository of technical publications. Its collections consist of 20 million items, including books, magazines, dissertations, Ukrainian and foreign standards, technical specifications, and special catalogs of Ukrainian- and foreign-manufactured products. One of the most important and popular departments among users part of the library is its patent department. There are approximately 18 million documents acquired from 57 countries in the patent department. There is a complex of different catalogs, card files, and electronic databases that allow retrieval of information.^[26]

The Central Library of the Ukrainian Association of the Blind

Founded in 1936, the library is an important educational and cultural center for visually impaired people.^[15] The library collection consists of about 170,000 items, including talking books, Braille books, Ukrainian and Russian audio periodicals (Gorizont, Obrii, Zdorov’ia, Svit

liudyny), CDs, and descriptive videos. It includes materials in Ukrainian, Russian, Polish, Romanian, Bulgarian, and Esperanto, among other languages. The library provides reference and information services for users.^[3] The Central Library for the Blind has, for many years, been the distributor of Ukrainian and Russian Braille Bible excerpts to sight-impaired people all over Ukraine. The library sends Bible Portions to 78 other libraries for the blind throughout the country.^[27] Annually, the libraries for the blind serve 40,000 readers.^[15]

CONCLUSION

The libraries have always played an important role in the history and culture of Ukraine. They have preserved the rich Ukrainian heritage and have served as the frontline resource in education and as the heralds of new ideas. Recent changes in political situations have greatly affected Ukrainian society and libraries. The libraries of Ukraine are now active participants in the international library society and are becoming a contributing part of the world information force. Now Ukrainian librarians can discover the accomplishments of their colleagues abroad and share their own experiences in the field of library science.

ACKNOWLEDGMENTS

I would like to thank my colleagues from the Vinnytsia Regional Scientific Library (Ukraine), Tetiana Yaroshenko from the Library of the National University “Kyiv-Mohyla Academy,” and Valentyna Pashkova from the Ukrainian Library Association for sharing information. My special thanks to my friend, Michael Wood, for all her help and support.

Undergraduate Library Collections *[ELIS Classic]*

Amy M. Kautzman

University of California, Berkeley, Berkeley, California, U.S.A.

Abstract

The undergraduate library is a collection specifically set aside to serve the research needs of undergraduate students. Generally, it is in a building separate from the main research collection. Historically, it is a recent phenomenon, located primarily in the United States within the past 50 years. This entry will examine the reasons why this special collection is desired and developed, and continues to be useful in today's hyper-information-rich culture; and will look at the history, architecture, collections, and services of undergraduate libraries.

BACKGROUND

An undergraduate library's purpose is to serve expressly the needs of students in their first 4 years of college. Although the collection is not limited to resources that are required for an undergraduate education, it is expected that the majority of the student's research needs will be met with finely tuned holdings. Undergraduate libraries are most often found at large research institutions where there are multiple libraries, many of which are highly specialized. In effect, undergraduate libraries are designed to help the inexperienced student researcher find a way through too many research options. According to the American Library Association (ALA), "as a group, most first-year students share the following characteristics:

1. They do not yet have the sophisticated research skills needed to exploit the research library's potential.
2. They are intimidated by the complexity and size of a large library system.
3. They are often reluctant to ask for assistance in the use of a library.
4. They are unaware of the many services and resources that are available in university libraries."^[1]

Many undergraduates lack research experience and sophistication. Although a small college library is better able to direct users to materials, universities the size of University of California at Berkeley, Michigan, or Harvard are frustrating mazes of multiple libraries that confuse and discourage novice researchers. The undergraduate library makes space for young researchers in a complicated library system.

HISTORY

The yearning for a specialized library serving the undergraduate population is neither original nor recent. In 1601,

at the University of Uppsala, Olef Rudbeck proposed a duplicate library for undergraduates. He felt that it "should be set up in the main building for students who may always use them (the books) there."^[2] Not long after, in 1602, the Bodley Library (precursor to the Bodleian) opened. As early as 1608, the new librarian, Thomas James, inquired into building a special collection to better serve his young clientele. He received this response from Sir Thomas Bodley:

Your deuise for a Libarie for the yonger sort will haue many great exceptions, and one special force. That there must be an other keeper ordeined for that place. And where yow mention the yonger sort, I knowe what books should be bought for them, but the elder as well [as] the yonger, may hae often occasion to looke vpon them: and if there were any suche, they can not require so great a rowme. In effect, to my understanding, there is much to be saied against it, as vndoubtedly your self will readily finde, vpon further consideration. (Wagmen.^[3])

It is fascinating and telling to realize that the issues of staffing and audience were readily invoked in the nascent history of library management, in the end trumping public service for the presumed lack of funding.

In spite of Thomas James' request for a special collection, early library collections were not concerned with undergraduates. With nowhere near the number of publications that libraries now offer, books were rare, valuable, and not readily available. It was difficult to make books accessible to students, much less have duplicate collections, when folios were chained to the wall to discourage theft. In addition, the pedagogy of the day relied on rote memorization that did not require the use of a large number of books. The emergence of the research university model revolutionized old disciplines. Two countries, Scotland and Germany, developed the single-discipline professorial model we know so well. The advent of an industrial society, from around 1789 to 1939, transformed education.

Just as the division of labor segmented the work environment, so it came to effect the educational system. According to Harold Perkin, most universities were envisioned as seminaries, with a few other disciplines also taught. Schools had ignored the need for technically trained students, even as “the applied science and technology needed for the new manufacturing, mining, and transport industries had to be taught in new institutions”.^[4] Along with the expansion of disciplines in higher education came changes to the library’s collections. Although the early university libraries had strong “divinity” collections, along with law and science, the new education model, with its stress on research, emphasized growth in the subjects of literature, political thought, and natural sciences. As libraries collected more titles, the use of monographs went up accordingly.

The expanding curriculum did not immediately change undergraduate education. But over time, students began to desire access to the stacks and to a greater variety of titles. One solution was for student societies and student libraries to purchase and manage a selection of basic texts. Person^[2] notes that “student-owned libraries were particularly strong at Yale, Princeton, Columbia, and Dartmouth, and in some cases surpass(d) the college libraries themselves in holdings.” Harvard and others used a model of “house,” or dorm, libraries where each house owned a working library of titles necessary for research.

In 1857, Harvard students proposed a separate collection of books specifically for their needs. They pointed out the “utter inadequacy of the College library to meet the wants of undergraduates in their last two years.”^[5] In 1907, Columbia College, just down the road in New York City, listened to the students and developed the Columbia College Study, which became the first special library service directed toward undergraduates. Although the Columbia College Study was a step in the right direction, it did little more than highlight a service dilemma: How is a library to serve the deep research needs of graduate students and faculty while also supporting the very general needs of a large, inexperienced group of undergraduates?

Further complicating the issue, President Franklin D. Roosevelt signed into law the Servicemen’s Readjustment Act of 1944. Also known as the GI Bill, this law helped millions of veterans reacclimate to civilian and academic life. From 1946 to 1948, returning veterans made up almost 50% of all students. This influx of students overburdened libraries and universities, and caused a flurry of building and expansion matching the growth of the student body.

Widener Library (Harvard’s primary research library in the humanities and social sciences), always tight on space, became more crowded. How do we serve both the faculty and the growing number of undergraduate researchers? The answer came from Harvard in 1949 when Lamont Library, the first undergraduate library, opened to great anticipation. Keyes D. Metcalf, the Director of the

Harvard University Library at the time of Lamont’s completion, had strong objectives in mind for Lamont. These objectives, one could say, can still be applied to any successful undergraduate library, as follows:

1. To concentrate as far as practicable the library service for undergraduates in a central location;
2. To make the books readily accessible to the students;
3. To encourage general and recreational, as well as assigned and collateral reading.^[6]

The opening day collection of 39,000 titles (over 80,000 volumes) was a great success—unless you were a student from Radcliffe. Although students from both Harvard and its sister school, Radcliffe, were now allowed into the Widener stacks with a pass, it took until 1967 for women to be allowed into Lamont. Female students were barred from Lamont Library for fear that making the secluded stacks coed might distract students from their studies and encourage romantic trysts. Today, there are few limitations on which campus users can enter into an undergraduate library, with many faculty and graduate students enamored with the ease of use and open stacks.

ARCHITECTURE

Undergraduate libraries have many physical commonalities. Most have a modern architectural sensibility that comes from both a recent history and an embracing of the contemporary aesthetic of function over ornate form. The Lamont Library, for example, was the first modern building built on the Harvard campus to break from the neo-Georgian brick tradition. It has smooth lines, an abundance of large windows, burnished woodwork, and natural light in the tradition of mid 20th century architecture. Although nobody will deny that it is much easier to use than the Widener Library, Lamont did have detractors. An article in the *Harvard Crimson* pointed out that,

in the past five years, some of the enthusiasm for blonde wood and plate glass has evaporated, and unfortunately for Lamont, its machine-like, often submarine atmosphere has proved the main deterrent to its complete popularity. Nevertheless, by and large, the story of these five years is a success story.^[7]

The Moffitt Library, at University of California at Berkeley, also incorporates a contemporary design. The modernist concrete frame building is meant to suggest a Japanese garden pavilion but has instead been nicknamed the “parking garage.” Critics aside, the radical way in which undergraduate libraries simplified research encouraged a whole new approach to the library as a “place.”

A successful undergraduate library will be located smack dab on undergraduate traffic routes. The University of Texas at Austin did a fabulous job in locating its undergraduate library between the student union building and the main library. Such libraries should be easily accessible with the open stacks and materials arranged with user ease in mind. Library services, such as reserve reading, a circulation desk, and a welcoming reference desk, are designed to be front and center on entering the building. Seating and study space is more important in a library where students gather for long periods of time. Crowded dorms, lack of quiet study space, and the desire to be near friends usually guarantee that the undergraduate library is a popular destination. Other special resources such as media and computer centers as well as group study rooms are incorporated into the design. Undergraduates use these services more heavily than senior researchers; thus it makes sense to place them in an easily accessible location. It is also true that undergraduates incorporate new technologies into their lives more readily. Therefore many undergraduate libraries are the first to add cutting-edge technologies and new media into their services.

When Harry H. Ransom (Main University Vice President and Provost, at the University of Texas at Austin) conceived of the undergraduate library, he understood the contemporary reasons for building a specialized collection. However, he also understood the shifting nature of academics when he outright acknowledged the need for an undergraduate program to mutate.

Its (the library's) planners have resisted all influences to make the place a mausoleum of dead ideas attended by the undertakers of polite scholarship. No amount of planning can anticipate the opportunities and obligations that a dynamic educational program will produce from year to future year. Equally important inhabitants of the mere building, of course, will be both the immortal words and the growing, mortal minds. Therefore the really significant changes that lie ahead will be mental rather than architectural.^[8]

Ransom is an example of the forward thinking that allowed University of Texas at Austin to develop innovative partnerships with campus computing, resulting in its highly successful web-based library education site, TILT.^[9]

It is not an overstatement to emphasize the importance of the library to the undergraduate. As a sense of place, it defines the learning experience, the socializing of students, and the exploration of new subjects. In many institutions, the undergraduate library is the central academic experience. What we do not know is how future library use and technology will affect the infrastructure of the library. Seers have been announcing the end of brick-and-mortar libraries for over a decade. And although building and collection use has changed phenomenally, the desire on the part of faculty and students for a place to be surrounded by books (and computers) is unabated.

COLLECTION DEVELOPMENT

The onus of an undergraduate collection is to reflect and support the institution's curriculum. The collection is seen as an ever-changing reflection of classic readings and current topics. In general, undergraduate titles circulate for a shorter period of time, reflecting the tighter schedule and general nature of their scholarship. The need for weeding is ongoing, and it is the mission of the selector to keep abreast of new classes and departments. Being that it was first, the Lamont Library card file became the standard that latter undergraduate collections were built on. The University of Michigan's Shapiro Undergraduate Library holdings were also referred to as a supreme example of a public university's undergraduate collection. Static lists of titles, in the long run, were not very useful in building dynamic collections. In 1964, the ALA and the Association of College and Research Libraries began to publish *Choice: Current Reviews for Academic Libraries*. *Choice's* purpose was to provide reviews of recently published books that best fit in an undergraduate collection. *Choice* subject editors choose a limited number of titles that are then reviewed by librarians. As the *Choice* web site says, their reviewers are

selected for their subject expertise, their active involvement with undergraduate students and curricula, their diverse viewpoints and backgrounds, and their sensitivity to scholarly trends. Reference publications are reviewed by practicing academic librarians, many of whom are subject specialists with advanced degrees.^[10]

In today's collection climate, approval plans are often the default for building undergraduate collections. A librarian with a solid understanding of a user's needs and the ability to fine-tune an approval plan can receive shelf-ready books more quickly than ever.

When building or maintaining an undergraduate collection, ALA encourages a well-thought-out collection policy that considers the following:

1. Because many undergraduate courses require large numbers of students to use the same library materials, direct curriculum support will be provided through reserve collections and through purchase of multiple copies of items with high demand.
2. Undergraduate libraries provide effective access to information resources through reference sources in a variety of formats. Reference collections in undergraduate libraries should concentrate on the more standard and interdisciplinary indexes and sources. Periodical collections should emphasize the titles covered by these indexes.
3. Subject coverage of collections in undergraduate libraries encompasses a broad range of disciplines that offer the information needed for papers, speeches, and projects required in the wide variety of courses taken

by undergraduates. More specialized and advanced needs will be met by specific referral to other library sources on campus.

4. The library experience of undergraduates should encourage them to seek information of personal interest. Collection policies should include access to information on current events, cultural interests, careers, and recreational reading, among others, to encourage exploration of information resources as a part of everyday life. Because of the special nature of undergraduate libraries, collection policies should include withdrawal practices. Collections should be dynamic and responsive to the needs of a changing curriculum and clientele.^[11]

The joy of a well-developed undergraduate library is that it informs and serves all university researchers while staying current and useful. For upper-level undergraduates as well as professors and graduate students, the undergraduate library is an excellent starting place. For deeper information needs, there is always the option of visiting the research library.

CONSTANTLY MUTATING PURPOSE

Throughout the decades, the expansion of undergraduate libraries continued, peaking with 30 undergraduate-specific libraries being added from 1960 to 1970.^[12] The increase of undergraduate libraries matched the growing number of students enrolled in college. However, the 1970s saw a decline in the number of undergraduate libraries as missions changed, space was reallocated, and libraries were merged or shut down. Henry W. Wingate, author of *The Undergraduate Library: Is It Obsolete?* claimed,

The reasons for the disenchantment with the undergraduate library concept can be traced to 1) changes in curriculum and teaching methods, and 2) tighter library budgets that preclude the extensive duplication of books and services required, and, perhaps most importantly, the realization that a separate facility works to deprive the undergraduate of a learning experience that only a large research library can offer.^[13]

Undergraduate libraries succeeded when they developed a well-thought-out mission that supported a user-centric focus. In Irene Braden's 1970 book, *The Undergraduate Library*, she lists six categories in which undergraduate libraries differ from research libraries, as follows:

1. Providing open access to the collection to avoid the difficulties of the closed stack system;
2. Centralizing and simplifying services to the undergraduate;

3. Providing a collection of carefully selected books, containing the titles all undergraduates should be exposed to for their liberal education, as well as incorporating the reserved book collection;
4. Attempting to make the library an instructional tool by planning it as a center for instruction in library use, to prepare undergraduates for using larger collections, and to staff it with librarians interested in teaching the undergraduates the resources of a library and the means of tapping those resources;
5. Providing services additional to those given by the research collection;
6. Constructing a building with the undergraduates' habits of use in mind.^[8]

In effect, Braden took the physical qualities of the earliest undergraduate libraries (a distinct building and collection) and added a pedagogical purpose that would build critical learning skills into library research. Braden was a harbinger of the importance of instruction in undergraduate libraries—a trend that has yet to slow down.

Libraries have become more complicated as online resources multiply and universities develop multiple catalogs to handle their metadata. The need for understanding how information is researched, published, and made available is one of the most important tools we can pass on to our students. Critical thinking skills—the ability to develop, question, test, and prove one's own as well as another's hypothesis—are the basic purpose of undergraduate education. The undergraduate library is often the locus of discovery. Paula Kaufman (Librarian, University of Illinois, Urbana-Champaign) states, "There is a renewed interest in undergraduate teaching in research universities. Also we feel acutely the need to provide a different kind of instruction to our students, most of whom are undergraduate students."^[14]

Many of our students feel they are competent online researchers. They troll the Internet, find full-text articles, and link to sites that fulfill their curiosity. The reality is that they do find information, just as students were able to find titles in the research library, when allowed access. The question asked by instruction librarians throughout the 1980s and 1990s is broader: Now that you have found information, do you know how to evaluate it, then find even more that is on target for your research and ever-growing information needs?

UNDERGRADUATE LIBRARIES TODAY

The 1990s were a time of refocusing on the undergraduate library's purpose, as well as questioning the purpose of all libraries. As the Internet and online resources threatened funding and a lessening of faculty support, innovative libraries looked to transform how they were viewed and used.

One unusual example is the David Adamany Undergraduate Library at Wayne State University. Built in 1997, it is the newest undergraduate library in the nation. The rethinking of a library for undergraduates culminated in a building with 500 computer workstations providing access to electronic resources and a media collection of videos, DVDs, laser discs, and audiotapes. A one-stop service, the undergraduate library also provides students with information on careers and student survival skills. And yes, it still holds books and periodicals.

UWired, at the University of Washington, is the perfect example of the library collaborating with the Office of Undergraduate Education and Computing and Communications. This amalgam promoted “broad-based discussions, experimentation, and analysis about the following areas:

- Innovation in teaching and learning with technology tools;
- Fluency in information technology;
- New ways for students and faculty to access technology-enabled tools and resources.”^[15]

Those three points could not be more different, and yet similar, to the reasons for constructing the Lamont Library more than 50 years ago.

In their article, “One Size Doesn’t Fit All: Designing Scaleable, Client-Centered Support for Technology in Teaching,” Mark Donovan and Scott Macklin explain that,

though UWired began as an initiative to support student uses of technology, the UWired partners understood that parallel efforts aimed at supporting teachers were a necessity. UWired’s efforts to support faculty were initially confined to workshops and faculty showcases. These early efforts were driven by the energies of those faculty who were pioneering educational uses of then-new technologies such as email and the Web.^[16]

Working in space donated by the undergraduate library, UWired became highly lauded as a model of instruction/library/technology partnership.

Information commons and information gateways are two other terms that have gained relevancy. The term *commons* refers back to community, a collective entity. It is the library trying to recreate a sense of place, shared community, and information sharing. The gateway concept relates to the opening of an access point, perhaps to the commons. Interestingly enough, the physical undergraduate collections at the University of Washington are kept in the Odegaard Undergraduate Library and Computing Commons, whereas the University of Indiana has the Information Commons/Undergraduate Services. The traits shared by information commons and gateways are not unlike those shared by the earliest undergraduate libraries.

For many libraries, the collection focus has changed to a combination of virtual and physical resources—relying

heavily on computers and wireless access. Yet the sense of purpose continues with the focus on undergraduate-specific collections as well as common study space and furniture appropriate for lounging. In addition, most libraries now incorporate a café and/or coffee shop. The café is a certain moneymaker, replacing the once-golden copy center. But more than that, it is a social center that is yet another hook for pulling in users. In the past, smoking was the number one social consideration when designing an undergraduate space. Today, it is coffee.

UNDERGRADUATE LIBRARY ORGANIZATIONS

The ALA’s subgroup, the Association of College and Research Libraries, sponsors the Undergraduate Librarians Discussion Group.^[17] Known as UGLI, they are the primary group for conversation on subjects of interest to the operation of undergraduate libraries. They support a basic web site and list of active undergraduate libraries. The endnotes from previous citations refer to the ALA web site where two important undergraduate library documents are located. *The Mission of a University Undergraduate Library: Model Statement* and the *Guidelines for University Undergraduate Libraries* are useful reads for any library that serves undergraduates, even if undergraduates are not the primary audience of collection. Directly below is a list of self-designated undergraduate libraries. Although the numbers are down from the peak in the 1970s, it is still an impressive list of institutions that have made a symbolic, budgetary, and pedagogical priority of our “yonguer sort.”

CURRENT UNDERGRADUATE LIBRARIES

Columbia University (New York, NY)
 Philip L. Milstein Family College Library
 Cornell University (Ithaca, NY)
 Uris Library
 George Mason University (Fairfax, VA)
 Johnson Center Library
 Harvard University (Cambridge, MA)
 Lamont, Harvard College Library
 Indiana University-Bloomington (Bloomington, IN)
 Undergraduate Library Services
 Purdue University (West Lafayette, IN)
 John W. Hicks Undergraduate Library
 Southern Illinois University at Carbondale
 (Carbondale, IL)
 Undergraduate Library Division (in Morris)
 Stanford University (Stanford, CA)
 Meyer Library
 State University of New York at Buffalo (Buffalo, NY)
 Oscar A. Silverman Undergraduate Library
 University of Arizona (Tucson, AZ)
 Integrated Learning Center

University of California at Berkeley (Berkeley, CA)
Moffitt Undergraduate Library
University of California at Los Angeles (Los Angeles, CA)
College Library
University of California at San Diego (San Diego, CA)
Center for Library and Instructional Computing Services (CLICS)
University of Chicago (Chicago, IL)
Harper Library
University of Illinois at Urbana-Champaign (Urbana, IL)
Undergraduate Library
University of Michigan (Ann Arbor, MI)
Shapiro Undergraduate Library
University of North Carolina at Chapel Hill (Chapel Hill, NC)
R. B. House Undergraduate Library
University of Southern California (Los Angeles, CA)
Thomas and Dorothy Leavey Library
University of Texas at Austin (Austin, TX)
Undergraduate Library
University of Virginia (Charlottesville, VA)
Clemons Library
University of Washington (Seattle, WA)
Odegard Undergraduate Library
University of Wisconsin-Madison (Madison, WI)
Helen C. White College Library
Wayne State University (Detroit, MI)
David Adamany Undergraduate Library^[18]

CONCLUSION

The one constant in the half century since Lamont was built is its focus on undergraduates and their research needs. It is important that developing scholars have a safe place in which to learn how to use the multitude of research options available to them. The building design is as important as the selection of the collection and the service configurations that help acquaint users with the tools. As libraries become ever more complicated and as students are faced with a growing number of full-text resources, students will need guidance in formulating their research strategies and selecting appropriate and trustworthy artifacts (physical or not).

Although many libraries have changed how they serve undergraduates, there will most certainly be a number of large research libraries that will continue to support their undergraduate libraries as part of their research and library mission.

UNESCO: Communication and Information Sector

Joie Springer

Information Society Division, UNESCO, Paris, France

Abstract

This entry presents a brief overview of UNESCO and the activities implemented by its Information Society Division in pursuit of its overall mandate to promote the free flow of ideas and universal access to information. It looks at the origins of the program, its current strategic objectives, and some of its activities, especially those relating to libraries and archives, which are designed to meet the development needs of the world's population.

INTRODUCTION

For 60 years, the United Nations Educational, Scientific and Cultural Organization (UNESCO) has had the responsibility of ensuring the spread of knowledge through improved access to printed and published materials. Much of this is available in libraries and archives, which are the traditional caretakers of knowledge. This entry is intended to provide an understanding and appreciation of the work of UNESCO in the development of libraries and archives and the new thrusts in information management in the cyberspace age.

UNESCO was founded in the aftermath of the Second World War as a specialized agency with lofty ideals of creating and maintaining a culture of peace, by changing mentalities. To achieve this goal, it has sought to promote dialog based upon mutual respect and dignity of different cultures by maintaining, increasing, and diffusing knowledge as decreed, in part, in its constitution, by assuring the conservation and protection of the world's inheritance of books and monuments of history and science, as well as by encouraging cooperation among nations in all branches of intellectual activity, including the exchange of publications, objects of artistic and scientific interest, and other materials of information.

Policy and direction are approved sexennially (Medium-Term Strategy) by the General Conference of Member States and are concretized in its biennial programs and budgets, which focus on development priorities. Currently, the major emphasis is on attaining the United Nations Millennium Development Goals which, inter alia, target the reduction of global levels of extreme poverty, attaining universal primary education, elimination of gender disparity, and development of strategies for sustainable development.

These ambitious goals are achieved through a pragmatic approach covering the five Program Sectors of UNESCO (Education, Natural Sciences, Social and Human Sciences, Culture, Communication, and Information). UNESCO's

current *Medium Term Strategy for 2008–2013* (<http://unesdoc.unesco.org/images/0014/001499/149999e.pdf>)

proposes that the Organization adopt a bolder policy with respect to national development priorities, including, in the information field, for it to assume a stronger leadership role in the provision of universal access to knowledge. To this end, it has set “building inclusive knowledge societies through information and communication” as one of its overarching objectives.

Consequently, the priority of promoting the free flow of ideas and universal access to information is high among the principal strategic objectives of the Communication and Information Sector; the others being promoting the expression of pluralism and cultural diversity in the media and world information networks as well as promoting access for all to information and communication technologies (ICTs). The sector is composed of three divisions, namely

- The Communication Development Division
- The Division for Freedom of Expression, Democracy, and Peace
- The Information Society Division

The Information Society Division has been assigned the responsibility of steering policies for universal access to information, which includes the formulation of national information policy frameworks; the preservation of documentary information in all its forms; building information literacy capacities; encouraging the development of knowledge societies and fostering ethical considerations for the information society.

The Division was established at the start of the twenty-first century to lead information developments and respond to the challenges of the third millennium. It was born of a merger of the former General Information Program (PGI) and the Intergovernmental Informatics Program (IIP). PGI had in turn been established in 1977 in response to the convergence between scientific and

technological information (UNISIST) and documentation, libraries, and archives (NATIS) whereas IIP had been set up in 1985 to develop and implement concrete projects in the field of informatics.

UNESCO's Department of Documentation, Libraries and Archives (DBA) created in 1966 dealt with the development of information infrastructures while the UNISIST program had been established in 1972 as an intergovernmental program to coordinate cooperation in the field of scientific and technical information. However, the recommendations of the Intergovernmental Conference on the Planning of National Documentation, Library and Archive Infrastructures (NATIS) organized by DBA in 1974 revealed overlaps with those formulated by the 1971 UNISIST Conference. Duplication in the Programs led to proposals for a merger of the two as the PGI under an Intergovernmental Council that would be responsible "for guiding the conception and planning of the program, in particular by making recommendations on the content of the biennial programs and budgets and the Medium-Term Plans, reviewing the results achieved, recommending priorities, and encouraging the participation of Member States in the implementation of the program."

The retention of the name "UNISIST" was recommended by UNESCO's General Conference "for appropriate use" and can still be found on a number of documents produced by the Information Society Division, but although documentation, library, and archives infrastructures remain integral to the Program, the acronym "NATIS" was dropped from UNESCO usage.

The information program has always been both interdisciplinary and intersectoral with applications for all branches of knowledge and sectors of human activity even though structures, lines of emphasis, and approaches have been modified over the years as philosophies and technologies evolved. An evaluation of the Program (<http://unesdoc.unesco.org/images/0008/000805/080582eb.pdf>) provides more in-depth information on the history, activities, and accomplishments of PGI during its first 10 years.

IIP, on the other hand was established in order to "strengthen international cooperation and national efforts devoted to the training of specialists, the development of infrastructure, the definition of national policies, and the better recognition of the role of informatics."

With the information revolution, an increasing overlap of the two programs was perceived, as both were progressively concentrating their activities on two main areas: content for the information society, and building "infostructure" through training, the establishment of information policies, and the promotion of networking. UNESCO's Director-General therefore suggested in 1996 that they would be best served by a single secretariat and that a new program should be designed to meet the needs of the information age.

Following a wide consultative process guided by an Ad Hoc Working Group, the Information for All Program

(IFAP) was created as a platform for global discussion on information access, enabling participation of all in the global information society, and on ethical, legal, and societal consequences of the use of ICTs. IFAP provides a framework for international cooperation and partnerships in the information field by developing strategies and tools to narrow the digital divides of the information society. It is guided by an Intergovernmental Council composed of 26 members representing all geographic regions of the world. Its secretariat is assured by the Information Society Division.

An evaluation in 2006 concluded that IFAP had achieved limited success only as the scope of its action had, to a large extent, been overtaken by the World Summit on the Information Society (WSIS) process and this action is now being implemented by other stakeholders. To maintain its relevance in the information age, IFAP's program has been reviewed, and it has been tasked to attain five main strategic targets: information for development, information accessibility, information literacy, information ethics, and information preservation with libraries and archives playing a major contributory role in achieving each of these objectives.

While other bodies and organizations have concentrated on providing digital connectivity as well as the technology to help leapfrog into the information age, UNESCO has tended to place more emphasis on its concept of Knowledge Societies, that is, facilitating access to content and building capacities to make effective use of information. In this regard, it has identified four anchors on which to ground its principles of inclusion and pluralism that are based on human needs and rights. These are knowledge creation, knowledge preservation, knowledge dissemination, and knowledge utilization.

Our organization has been working on a wide variety of approaches and actions to help build national and regional capabilities and its contribution to the WSIS succeeded in broadening the debate to the point where the final Declaration of Principles and the Plan of Action of the Summit entrenched the four principles espoused by the organization, namely freedom of expression; universal access to information; the promotion of cultural diversity, multilingualism, and local content; and equal access to education. The Action Plan reflects UNESCO's belief in the importance of "democratization of access" and focuses on the ability to use technology rather than on technology itself. This means that in capitalizing on the opportunities offered by ICTs, greater attention is being paid to capacity building in support of societal transformation and on the adoption of best practices in e-governance services, with particular focus on addressing the obstacles to progress, especially in developing countries.

The role of information in addressing development issues has not always been fully understood by some governments or countries. Knowledge-based and knowledge-led development has the potential to achieve many of the

targets set under the Millennium Development Goals especially those relating to universal primary education and sustainability, on condition that there is equitable access to and use of requisite information and expertise. For this reason, emphasis is being given to *information for development* as a strategic goal of the IFAP and the Information Society Division, and a major focus of UNESCO's policy is to contribute to the formulation of national information policies and laws that reinforce the position of libraries, archives, and other knowledge institutions to fully accomplish their function as content providers contributing to continued access to recorded information.

This is particularly applicable in developing countries, which face problems caused by globalization and its impact on their societies. Globalization is largely driven by ICTs, which are radically transforming societies, both modern and traditional, and shaping patterns of growth, and wealth creation. They can provide for the expansion of home-based job opportunities and offer potential benefits to all of humanity. But sadly, in many regions of the world, this is still an unrealized dream. So, while information or knowledge has become a principal force of social transformation, much of it still remains out of the reach of those for whom it is absolutely indispensable to revolutionize their lives in order to rise from the misery of poverty. Countries that are technologically equipped to maximize the advantages of the information society are speeding along the information highway, while others that need to invest much more in human resources or infrastructure development are mere hitchhikers. However, inequitable access plagues all countries, not just the poorer ones, and increases the divide within, and among, nations.

It is therefore incumbent on governments and local authorities to reduce these divides, and as information is largely channelled by libraries and archives, they can have a key role to play in enabling all sectors of society to receive, generate, and/or disseminate information on all areas of interest, in addition to being a facilitator between the policies of, and services provided by, local and national government and the community or nation they serve. The challenge for these institutions is to provide access to content in support of a greater social qualitative change while respecting their individual charters. By promoting empowerment and participation through equitable access and sharing of knowledge, community information points contribute fundamentally to development.

For an information component to be successfully integrated into development plans, the capacity to access and use information is a prerequisite. While access to ICTs can enable greater participation in the benefits of knowledge societies, people must be adept not only in their use, but, as defined in the Alexandria Proclamation which was adopted by the High Level Colloquium on Information Literacy and Lifelong Learning in Egypt in November 2005, they must also have the ability to "seek, evaluate, use, and create information effectively to achieve their

personal, social, occupational, and educational goals." In other words, they must be information literate.

All libraries, especially public and community libraries, must be able to contribute to achieving *information literacy* and part of UNESCO's main strategy in this area consists of awareness-raising about the importance of information literacy at all levels of the educational process and of establishing guidelines for incorporating information literacy issues in curricula. A key plank in this strategy is the integration of libraries into information literacy programs as they provide resources and services in an environment that fosters free and open inquiry and serve as catalysts for the interpretation and application of knowledge in all fields of learning. UNESCO is therefore developing a conceptual framework whose objectives, strategies, and actions will contribute to both critical understanding and active participation by enabling the interpretation of data and making of informed judgments by users of information sources.

To this end, the Organization has conducted international meetings, funded projects, published guides, and created an Internet portal to sensitize those interested in learning about the concept and its applications. A number of workshops across the globe have provided trainers with the basic skills required to transmit to others how to effectively access and assess information from different sources. Much of its work in the field of information literacy is being conducted in cooperation with the International Federation of Library Associations and Institutions (IFLA). This includes the creation of an international directory database (<http://www.infolitglobal.info>), in English and Spanish, of information literacy resources. These resources can be adapted or be used as examples in building new information literacy applications or to assess achievements and plan future policies.

As mentioned earlier, technological advances have given rise to new opportunities, but they have also led to concerns about the use of information, especially digital information, which can be easily manipulated. UNESCO has consequently initiated an international debate on *information ethics* (infoethics) to examine the ethical, legal, and societal aspects of the application of ICTs. While acknowledging the right to freedom of expression, universal access to information, especially public domain information and the right to education as being of primary importance, other rights including the right to privacy and proprietary rights must also be respected.

The challenges and opportunities presented by ICTs require that appropriate mechanisms and safeguards are in place to guide development and enable policy makers to explore benefits and risks especially for the protection of the more vulnerable members of their community, as well as striking the balance between intellectual property rights and the rights of users to access information. One option that is being explored is the possible establishment of a national advisory body composed of all stakeholders

to address ethical issues such as peace, upholding fundamental values of freedom, equality, tolerance, shared responsibility, and respect for nature in order to establish a national framework.

IFAP's strategic objective of *information accessibility* takes into account the wide range of factors that can block access to sources of information with a consequent impact on development. ICTs have transformed, for better and for worse, traditional practices that provided access to information needed for development or to address areas of concern. Issues related to copyright, piracy, and protection of data have led to the impositions of conditions that restrict access to sources of information and knowledge, which used to be easily available in the past. At the same time, the Internet has opened up new and broader opportunities with the potential to allow unprecedented numbers of people to share and obtain information from wider sources and in their own language. Admittedly, a huge percentage of the world's population has yet to publish content in native languages but the expansion of digital services and connectivity should lead to an evolution of this situation. Furthermore, the incremental growth in the use of cell phones is viewed as an exciting possibility for the transmission and reception of information in local languages in future.

UNESCO's *Recommendation concerning the Promotion and Use of Multilingualism and Universal Access to Cyberspace*, which was adopted in 2003, has been important in this regard as it has opened new vistas promoting multilingualism and multilingual search tools on the Internet with a corresponding increase in linguistic diversity on the Internet. This is an important step in protecting some of the world's endangered languages. UNESCO is further encouraging research to assess the extent of progress in achieving a multilingual cyberspace so as to adjust its area of focus as required. Emphasis is currently being given to activities that will lead to the inclusion of additional languages and the dissemination of more local content in cyberspace, as well as to the development of Internationalized Domain Names (IDNs).

Accessibility to information is also boosted by UNESCO's promotion of Free and Open Source Software (FOSS), Open Educational Resources (OER), and its Open Training Platform (OTP) while contributing to building capacities in their use. It has focussed on the development of open information processing tools, interoperability standards, metadata, and more, that permit equitable access to the use of ICTs. These can also be particularly beneficial to the approximately one-third of the world's population, which is affected by disability or reduced mobility by removing their isolation from the outside world and aiding their social and economic participation in society. UNESCO's program helps to promote the rights and needs of people with disabilities, including increasing awareness of accessible technologies and supporting their development as well as publishing

accessibility guidelines for community information centers to cater to people with disabilities.

Much of constructing knowledge societies relates to ensuring adequate access to information. However, the flip side of the coin, or *information preservation*, is of equal, if not more, concern to UNESCO since the disappearance of information leads to an impoverishment of humanity.

From the founding of UNESCO, its documentary heritage program, whether as an independent unit or as a Division attached to a Program Sector, has always had one constant goal, that of enabling access to the knowledge, and information produced anywhere in the world, and ensuring its continued availability through preservative actions. In fact, UNESCO's first budget made provision for the reconstruction of libraries; and libraries and archives continue to be among its priorities some 60 years later, even as their form and role have changed in response to technological progress or societal transformations.

Training and capacity building for information personnel have been traditionally supported by UNESCO since its creation. In addition to sponsoring workshops, training courses and symposia, the Organization has set up two information portals: the *UNESCO Libraries Portal* (http://www.unesco.org/webworld/portal_bib) and the *UNESCO Archives Portal* (http://www.unesco.org/webworld/portal_archives) as a public service access to online resources related to, or to issues affecting, the information profession. They include institutional Web sites, training, and job opportunities as well as other resources related to information management and to international cooperation in these fields.

Since 1946, the Organization has been involved in the construction, or reconstitution, of some of the major libraries of the world, including the Bibliotheca Alexandrina in Egypt, the National Library of Latvia, and the rebuilding of the National and University Library of Bosnia and Herzegovina following its destruction in 1992. It has also contributed to establishing library expertise in most countries of the world; provided assistance in the move from traditional to electronic information management; and advised on coping with technological obsolescence, among other activities, in enabling libraries to contribute to lifelong learning, economic, and personal development as well as promote preservation of heritage.

Apart from serving as physical or virtual information access points, libraries have a social responsibility to eliminate barriers to knowledge, to constructive participation, and the development of democracy. The enormous potential of libraries is still largely untapped but their mix of resources and services provide for equal and democratic access to information.

In 1979, UNESCO created its Records and Archives Management Program (RAMP) in cooperation with the International Council on Archives (ICA) to support national development, archival training, and protect archival heritage. This was extended in 1980 to audiovisual

archives with the adoption of the *Recommendation for the Safeguarding and Preservation of Moving Images*. To preserve this heritage, UNESCO works closely with a group of NGOs under an umbrella structure better known as Coordinating Council of Audiovisual Archives Associations (CCAAA) (<http://www.ccaaa.org>) composed of AMIA, IASA, ICA, IFLA, FIAF, FIAT/IFTA, and SEAPAVAA whose main objective is to cooperate on influencing the development of public policy on issues of importance to professional audiovisual archivists.

UNESCO's archives programs have achieved significant gains through tangible outcomes such as the publication of model legal guidelines for the establishment of archives or the organization of the highly successful Joint Technical Symposia (JTS). Other projects include promoting the creation of human rights archives particularly in countries in the process of transition to democracy. These archives are of fundamental importance as evidence supporting victims' rights for reparation.

Yet, despite all efforts to protect and safeguard documentary heritage, threats to its existence continue to be a cause of alarm as natural disasters, chemical decomposition, wars, negligence, deliberate destruction, ignorance, and obsolescence contribute to losses with drastic consequences, as millions of items have either disappeared, or are on the verge of doing so. Conservative estimates are that more than 80% of the early films have been deliberately destroyed or have otherwise been lost. A graphic picture is painted in "Lost Memory: Libraries and Archives destroyed in the Twentieth Century" which was commissioned by UNESCO to obtain accurate information on the losses that occurred in the twentieth century alone.

This dramatic situation called for an urgent response and in 1992, UNESCO created the *Memory of the World Programme* (<http://www.unesco.org/webworld/en/mow>) as its flagship project to protect and promote the documentary heritage. The objectives of the Program are

1. To facilitate preservation, by the most appropriate techniques, of the world's documentary heritage.
2. To assist universal access to documentary heritage by encouraging the digitization of access copies of items while respecting legislative, cultural sensitivities, and other limitations to access.
3. To increase awareness worldwide of the existence and significance of documentary heritage, especially through the Memory of the World registers.

Four main strategic actions form the pillars of UNESCO's action to accomplish these goals and they can be summarized as

Identification of documentary heritage: This involves identifying documentary and assessing its impact for the country concerned. If it is determined that its

influence has been felt beyond national borders, or that the rest of the world would benefit from greater knowledge of the content, it could be listed on a Memory of the World register.

Raising awareness: This is especially important in regions where documentary heritage is endangered or awareness is low. Emphasis is given to preservation techniques and cooperation with professional bodies and associations.

Preservation: This is the main focus of the Program with particular attention accorded to heritage listed on a Memory of the World register. While the original document may be important as an object in itself, the content that resides on the carrier is the main focus of the program.

Access: Permanent access is the fourth goal of the Program as everyone has the right of access to their documentary heritage, the right to know it exists, and where to find it.

An International Advisory Committee of 14 members is appointed by the Director-General of UNESCO in their personal capacity to guide the planning and implementation of the Program and make recommendations concerning the inscription of nominations on the International Register, as well as the award of the UNESCO/Jikji Memory of the World Prize in recognition of outstanding preservation work.

Public impact and education are crucial in raising awareness of the vulnerability of information and the Memory of the World Register (<http://www.unesco.org/webworld/en/mow-register>) is the main component in this strategy. Currently there are 193 items from 80 different countries, 3 International Organization and 1 private foundation, and items cover all types of information carriers whether these are films or rock inscriptions, sound recordings or photographs, and tapestries or printed pages. Some are as recent as the 1986 Radio Broadcast of the Philippine People Power Revolution or as old as the Hittite cuneiform tablets from Turkey that date from the 2nd millennium B.C. Age is not a deciding factor; what matters is that the item is considered significant for the whole of humanity.

Paradoxically, modern documents are more endangered than older ones. The increase in digital materials and their short life expectancy have given rise to concerns about long-term preservation. Furthermore, as audiovisual and electronic documents are machine readable only, they need specific equipment and/or software to be retrieved. But playback equipment rapidly becomes obsolete resulting in the inability to access the content. Therefore, timely migration to newer technologies, operating systems, and software platforms must be factored into digital preservation policies and plans. Traditional preservation policies are irrelevant where digital materials are concerned.

Digital preservation, which is closely related to the strategic priorities for *information development* and

information accessibility, is a key component of the Memory of the World Program. Management of digital information has its own specific problems, added to which is the fact that it is still not yet universally known that the costs of systematically preserving digital information is higher in the long term than those required to preserve traditional analog documents.

UNESCO has developed a strategy for digital preservation, which is built on raising global awareness of the dangers facing digital heritage through its *Charter on the Preservation of Digital Heritage*, disseminating technical guidelines and capacity building in association with governments, policy makers, information producers, heritage institutions, and experts as well as the software industry and standard-setting organizations.

One recent initiative is the creation of a World Digital Library (<http://www.wdl.org>) being set up in collaboration with the Library of Congress in the United States. This project is designed to foster intercultural dialogue and understanding, preserve heritage, and facilitate greater access to knowledge. It is being implemented as part of the Memory of the World Program and a prototype, developed by the Library of Congress and UNESCO with partner institutions (Bibliotheca Alexandrina, the National Library of Egypt, the National Library of Brazil, the National Library of Russia, and the Russian State Library) was demonstrated in October 2007 ahead of a formal launch which took place on 21 April 2009 at UNESCO's Headquarters in Paris. It currently functions in Arabic, Chinese, English, French, Portuguese, Russian, and Spanish and libraries and archives around the world are encouraged to be part of this global endeavor.

CONCLUSION

This description of the major areas of the work of the Information Society Division relating to information

management and building knowledge societies covers but a small part of UNESCO's vast programs in education and learning, sciences, culture, communication, and information. Through its action and flagship projects, UNESCO has been able to contribute to achieving global development objectives such as those outlined in the WSIS's Plan of Action, or the Millennium Development Goals. This focus on creating "infostructures" and equipping all peoples, including disadvantaged, marginalized, and vulnerable groups, with the capacities to benefit from access to information and knowledge, remains true to its own constitutional mandate of spreading access to, and protecting, the world's sources of knowledge.

Unicode Standard

Joan M. Aliprand

Cupertino, California, U.S.A.

Abstract

The Unicode Standard is the single, universal character standard for all text, covering all of the world's writing systems, modern and ancient, as well as other elements of text such as technical symbols. Unicode provides the basis for the processing, storage, and interchange of textual data worldwide; it is fundamental to modern software and information technology protocols, and provides the character infrastructure of the World Wide Web. Unicode underlies modern systems and software products for libraries. Use of Unicode is explicitly included in the specifications for MARC 21 and UNIMARC records, and Z39.50 information retrieval, and is implicit in library standards and protocols based on Extensible Markup Language (XML) or Hypertext Markup Language (HTML).

INTRODUCTION

The Unicode Standard is the universal character encoding for the world's writing systems, and is fundamental to information technology worldwide. The first half of this entry covers key features of the Unicode Standard as well as the rationale for its development. The second half describes use of the Unicode Standard, with particular emphasis on library standards and protocols.

THE UNICODE STANDARD IN GENERAL

The Unicode Standard provides a uniform, universal architecture and encoding for all languages of the world, with over 100,000 characters currently encoded. Supporting the needs of all types of users, its coverage includes minority and historical scripts as well as those in common use. In addition, the Unicode Standard contains the largest set of characters for mathematical and technical publishing in existence, and an extensive set of musical symbols.^[1]

The Unicode Standard is the basis for the processing, storage, and seamless interchange of textual data worldwide. Unicode underlies modern software and Internet protocols, and provides the character infrastructure of the World Wide Web.^[2]

Much more than just a large character set, the Unicode Standard also defines how characters function. The extensive set of character attributes and the implementation algorithms specified in the Unicode Standard exist to ensure interoperability among implementations.

There are three constituent parts to the Unicode Standard: the book *The Unicode Standard*, the Unicode Character Database (UCD), and the Unicode Standard Annexes (UAXs). (All three constituent parts are available online;

The Unicode Standard is also available as a book. All updates to the constituent parts are published online.)

The Unicode Character Database (UCD) is a collection of data files that

- Contain the Unicode character code points and character names.
- Specify properties assigned to Unicode characters.
- Provide certain mappings between Unicode characters (e.g., 1:1 case mappings).

The UCD also contains explanatory documentation on UCD file formats and data in the files.^[3]

The 12 Unicode Standard Annexes (UAXs) cover significant features of the Unicode Standard in detail. Some UAXs, such as the Unicode Bidirectional Algorithm and the Unicode Line Breaking Algorithm, provide specifications for particular programming tasks.

DEVELOPMENT OF THE UNICODE STANDARD

By the late twentieth century, many different international, national, and corporate coded character sets had been developed for the processing, storage, and exchange of the characters of writing systems.^[4] Multilingual software applications had to deal with two serious problems: the same code value used to represent different characters, and different codes for a particular character encoded in multiple character sets.

When several character sets are used together in computer data, International Standard ISO/IEC 2022 provides a technique to distinguish them.^[5] Data in a particular character set is identified by means of a preceding "announcer," the *escape sequence*, so called because it begins with the control character *Escape* (1B hexadecimal).^[6] The International Organization for Standardization (ISO) administers

a registry that assigns a specific escape sequence to each character set submitted for registration. The problem with the ISO/IEC 2022 technique is that it is “stateful.” As a result, if identification of the applicable character sets is missing, correct interpretation and presentation of the coded data is not possible.

Both the MARC 21 and the UNIMARC formats permit use of multiple character sets, and specify the ISO/IEC 2022 technique of escape sequences to identify character sets.^[7–9] The problems described above may occur in library data encoded using multiple character sets.

MARC 21 and UNIMARC character sets both exhibit use of the same code value to represent different characters. In the individual MARC 21 character sets, for example, the value 66 (hexadecimal) represents five different letters: *Latin small letter f*, *Arabic letter noon*, *Cyrillic capital letter ef*, *Greek small letter epsilon*, and *Hebrew letter zayin*. The value 66 can also occur in 3-byte encodings of the East Asian Character Code (EACC).^[10]

Use of different codes for the same character is seen in the Extended Latin character sets of MARC 21 and UNIMARC: MARC 21 Extended Latin (a superset of ANSEL), and International Standard ISO 5426, respectively.^[11–13] The two character sets have 52 characters in common, but only one character has the same encoding. For example, the lowercase form of *Latin letter o with stroke* is encoded as 32 (hexadecimal) in MARC 21 Extended Latin but 79 (hexadecimal) in ISO 5426.

For over two decades, EACC was used in MARC 21 records for Chinese, Japanese, and Korean (CJK) data. Libraries in Asia, however, used either a national standard character set or an industry set such as Big-5. While many ideographs occur in all of these character sets, the various character sets encode the ideographs differently.^[14]

The primary goal in developing the Unicode Standard was to remedy the chaotic situation in multilingual software. The developers of the Unicode Standard envisioned a uniform method of character identification that would be a paradigm shift in multilingual computing. Unicode was designed to be universal, unambiguous, and efficient.

The Unicode Standard, Version 1.0 was published in 1991. There have been five major versions to date. The number of graphic characters in the Unicode Standard has grown from 28,282 in Version 1.0 to 100,507 in Version 5.1. Unicode is fundamental to modern information technology worldwide, and is used in all types of applications, from hand-held devices to massive databases.

THE UNICODE STANDARD AND ISO/IEC 10646

The Unicode Standard is code-for-code identical to International Standard ISO/IEC 10646, the *Universal Multiple-Octet Coded Character Set*, also known as the Universal Character Set (UCS).^[15] The Unicode Standard is the official way to implement ISO/IEC 10646.

The ongoing development of ISO/IEC 10646 is the responsibility of Working Group WG 2 of ISO/IEC JTC 1/SC 2, the subcommittee responsible for international standards for coded character sets. ISO/IEC JTC 1 is the Joint Technical Committee on information technology standardization of ISO and the International Electrotechnical Commission (IEC).

The Unicode Consortium and ISO/IEC JTC 1/SC 2 and its WG 2 have had a formal liaison relationship since 1992, and work closely together to coordinate and synchronize all additions to either standard, thus maintaining exactly the same character names and code points in both. Version 5.1 of the Unicode Standard is synchronized with ISO/IEC 10646:2003 plus its Amendments 1 through 4.

An implementation that is conformant to Unicode is also conformant to ISO/IEC 10646, but the reverse is not necessarily true because the Unicode Standard also specifies character properties and implementation algorithms.

DESIGN PRINCIPLES OF THE UNICODE STANDARD

The Unicode Standard is based on a set of 10 design principles: universality, efficiency, characters (not glyphs), semantics, plain text, logical order, unification, dynamic composition, stability, and convertibility. Except for a library-related comment on dynamic composition, this section is a condensation of Section 2.2 “Unicode Design Principles” from *The Unicode Standard, Version 5.0*.^[16]

Universality

The character repertoire of the Unicode Standard is intended to be universal in coverage, containing all the characters for textual representation in all modern writing systems and in most historic writing systems, as well as symbols used in plain text.

Efficiency

To keep character coding simple and efficient, the Unicode Standard assigns each character a unique numeric value and name. This unique identification of each character eliminates the need for cumbersome escape sequences and shift states. All of the Unicode encoding forms (described below) are self-synchronizing and nonoverlapping, facilitating access and searching within streams of characters.

Characters, Not Glyphs

Characters are abstract representations of the smallest components of written language that have semantic value.

Glyphs	Unicode Characters
À Á Â Ã Ä Å Æ	U+0041 LATIN CAPITAL LETTER A
à á â ã ä å æ	U+0061 LATIN SMALL LETTER A
п n ū	U+043F CYRILLIC SMALL LETTER PE
ه ه ه ه	U+0647 ARABIC LETTER HEH
fi fi	U+0066 LATIN SMALL LETTER F + U+0069 LATIN SMALL LETTER I

Fig. 1 Characters versus glyphs.

Copyright © 1991–2007 Unicode, Inc. All rights reserved.

Examples of such components are the letters, punctuation, digits, and other signs comprising natural language text and technical notation. The Unicode Standard encodes the character, not the various ways it can be visually represented.

Glyphs are the visual representations of characters as they are written or displayed, and can have various forms or shapes. Some writing systems require the use of particular glyphic forms. The form that the character takes when it is displayed (e.g., on a computer screen) is determined by text rendering software and the font currently in use.

Figure 1 shows the distinction between characters and glyphs. The illustration includes two examples of customary use: the positional forms for the Arabic letter *heh*, and the Cyrillic small letter *pe* with the italic alternatives used in Russia and Serbia, respectively.

Semantics

The Unicode Standard views character semantics as inherent to the definition of a character. A character’s semantics are determined by its identity, normative properties, and behavior. The Unicode Standard defines more than 50 different character attributes, called properties. The Unicode Character Database, an integral part of the Unicode Standard, provides machine-readable character property tables for use in implementations.

Examples of character properties are

- The name that formally and uniquely identifies the character.
- The script of the character.
- The general category of the character (letter, punctuation, symbol, white space, etc.).
- The numeric value when the character is a digit.
- Casing (upper, lower, title, and folding).
- Sequences of characters that are equivalent.
- Whether the characters may be used in program-language identifiers.
- How the character behaves in text with mixed directions, such as Arabic or Hebrew with English.

- Properties related to text boundaries, such as word breaks and line breaks.

Many of the properties assigned to characters are needed for algorithms that make use of them to produce expected results; for example, the Unicode Collation Algorithm, that specifies the default sorting behavior of text.^[17]

Plain Text

Plain text represents the basic, interchangeable content of text, not its appearance. Plain text contains enough information to permit the text to be rendered legibly, and nothing more. Additional formatting that affects the appearance of text (for example, language identification, font size, color, or hypertext links) is determined by higher level protocols and is not specified by the Unicode Standard.

Logical Order

Unicode characters are stored in logical order from first to last in the representation of text in computer memory. This approximates the order in which the characters are typed on a keyboard. When Unicode data is displayed, the text rendering process needs to recognize the directionality of each character and display text correctly for reading.

In some writing systems, such as Arabic and Hebrew, text is written and read from right to left. Text rendering becomes complicated when a document contains text in different directions (e.g., text in Arabic and English). The Unicode Bidirectional Algorithm specifies how mixed left-to-right and right-to-left horizontal text can be displayed in proper reading order.^[18]

Unification

The Unicode Standard avoids duplicate encoding of characters by unifying them within scripts across languages: characters that are equivalent are given a single code. Common letters, punctuation marks, symbols, and diacritics are given one code each, regardless of language, as are common East Asian ideographs (used to write Chinese, Japanese, Korean, and historical Vietnamese).

Dynamic Composition

Dynamic composition is the rendition of composite textual elements, such as accented letters or modern Korean Hangul syllables, from a sequence of characters. In other standards that cover accented letters or modern Korean Hangul, the accented letters or the Hangul syllables are usually encoded as single characters (i.e., as a static *precomposed* form of the textual element).

Librarians are familiar with the concept of dynamic composition; the use of separate diacritical marks with the letters of the English alphabet dates from MARC's beginning.^[19] EACC, in contrast, contains over 2,000 characters that are precomposed Hangul syllables.

Some text elements can be encoded either as static precomposed forms or by dynamic composition. For static precomposed forms (included for compatibility with certain standards), the Unicode Standard provides a mapping to the equivalent dynamically composed sequence of characters. Neither of these alternatives is prescribed as the "correct" one; each is merely equivalent to the other.

Stability

Certain aspects of the Unicode Standard must be absolutely stable across successive versions, so that implementers and users can be guaranteed that text data, once encoded, retains the same meaning. Most importantly, this means that once Unicode characters are assigned, their code point assignments cannot be changed, nor can characters be removed. Unicode character names are also never changed, so that they can be used as identifiers that are valid across versions. Stability guarantees also apply to certain important character properties.

Convertibility

For particular national, international, and corporate standards, character identity is retained for interchange of data between Unicode and these other standards. When a variant form or even character duplication exists in one of these standards, these characters are kept separate in the Unicode Standard instead of being unified. This guarantees accurate convertibility between the specified standards and Unicode.

UNICODE CHARACTERS AND ENCODING FORMS

This section presents an overview of the character content of the Unicode Standard, followed by a summary description of the three Unicode encoding forms (including UTF-8, which is specified for MARC 21 use). It condenses information from several sections of *The Unicode Standard, Version 5.0* (identified in the references).

Allocation of Unicode Characters

In computer processing, characters are represented as numbers. The *codespace* is the range of numbers available to code characters. A particular number in this range is called a *code point*. Each code point can be assigned to a character or designated for another use. The entire codespace of the Unicode Standard contains 1,114,112

unique code points which is more than sufficient for all known requirements.^[20]

It is convenient to think of the Unicode codespace as being divided into planes, with each plane containing 65,536 (64K) code points. The first 64K code points of the Unicode codespace are designated as the Basic Multilingual Plane (BMP); also called Plane 0. To date, only 6 of the 17 planes (0–2, 14–16) have defined uses.^[21]

The BMP contains all the common-use characters for all the modern scripts of the world, as well as many historical and rare characters. There are 53,333 characters allocated to the BMP (as of Version 5.1). Figure 2 shows the allocation areas on the BMP, with the General Scripts area shown in more detail on the right. The numbers to the left of each shaded bar are code point values in hexadecimal notation.^[6]

The General Scripts area encodes many of the scripts in modern use, such as Latin, Greek, and Cyrillic. The first 128 characters in the Unicode Standard (beginning the Latin block) are exactly compatible with those of the ASCII standard and ISO/IEC 646, the International Reference Version of ASCII.^[22]^[23] The first 256 characters are exactly compatible with International Standard ISO/IEC 8859-1, also known as Latin-1.^[24] Additional scripts are encoded in the Supplementary General Scripts area, after the Symbols area.

The CJK Miscellaneous area includes Hiragana and Katakana for Japanese, punctuation for East Asian scripts, and a large number of East Asian compatibility characters. The CJKV Ideographic area occupies a large part of the BMP. It contains unified Han ideographs for Chinese, Japanese, Korean, and historical Vietnamese, divided into two blocks: the Unified Repertoire and Ordering (20,924 characters), and Extension A (6,582 characters). The Asian Scripts area contains 11,172 Hangul syllables for Korean, plus several other Asian scripts.

The Surrogates area contains only surrogate code points used in the UTF-16 encoding form. The Private Use area contains 6,400 code points whose use can be defined by private agreements among cooperating users. The Compatibility and Specials area contains many compatibility variants of characters from widely used corporate and national standards that have other representations in the Unicode Standard.

Version 3.1 saw the first use of the supplementary planes with the addition of 44,946 characters including CJK Unified Ideographs Extension B on Plane 2. Version 3.2 added 1016 characters including a large set of symbols, which benefit mathematical and technical publishing. A large number of additional minority and historic scripts and various symbols and punctuation marks were added in Versions 4.0 through 5.1.

Unicode Encoding Forms

The Unicode Standard defines three encoding forms that allow the same data to be transmitted in a byte, word or

Fig. 2 Allocation on the Basic Multilingual Plane (BMP).
Source: *The Unicode Standard, Version 5.0*, Figure 2-14, p. 44.^[21]
Copyright © 1991–2007 Unicode, Inc. All rights reserved.

double word oriented format (i.e., in 8, 16, or 32 bits per code unit).^[25] All three encoding forms encode the *same* common character repertoire and can be efficiently transformed into one another without loss of data. All

three encoding forms need at most 4 bytes (or 32 bits) of data for each character. The Unicode Consortium fully endorses the use of any of these encoding forms as a conformant way of implementing the Unicode Standard.

UTF-8 is a way of transforming all Unicode characters into a variable length encoding of bytes. UTF-8 has these advantages:

- The Unicode characters corresponding to those of ASCII have the same byte values as ASCII.
- Unicode characters transformed into UTF-8 can be used with much existing byte-oriented software without extensive software rewrites.

The MARC 21 Specifications stipulate that when exchange records are encoded in Unicode, UTF-8 must be used.^[26]

UTF-16 is reasonably compact and all the heavily used characters fit into a single 16 bit code unit, while all other characters are accessible via pairs of 16 bit code units (*surrogate pairs*). UTF-16 is popular in many environments that need to balance efficient access to characters with economical use of storage.

UTF-32: Each Unicode character is encoded in a single 32 bit code unit when using UTF-32. UTF-32 is popular where memory space is no concern, but fixed-width, single code unit access to characters is desired.

The Unicode encoding forms correspond exactly to forms of use and transformation formats defined in ISO/IEC 10646. UTF-32 corresponds to the international standard's four-octet form UCS-4; UTF-8 and UTF-16 are defined in annexes of ISO/IEC 10646.

THE UNICODE CONSORTIUM

The Unicode Consortium was incorporated in 1991 as a nonprofit organization under the name Unicode, Inc.^[27] The Consortium's purpose is to develop, extend, and promote use of the Unicode Standard and other standards related to internationalization technologies.

Unicode Consortium members associated with academia and libraries include (as of October 2008): The University of California at Berkeley (Institutional Member), and Bibliothèque universitaire des langues et civilisations (BULAC). Columbia University, Ex Libris, Getty Trust Information Technology Services, Innovative Interfaces, LIB-IT, OCLC, SIL International, Utilika Foundation, VTLS, and the Wenlin Institute (all Associate Members).

Liaison Membership in the Unicode Consortium is offered by invitation only to standards organizations that have interests in common with the Consortium, particularly in technical areas. Liaison members associated with academia and libraries include (as of October 2008) Linguistic Society of America (LSA), National Endowment for the Humanities (NEH), National Information Standards Organization (NISO), Research Institute for Languages and Cultures of Asia and Africa (ILCAA) at the Tokyo University of Foreign Studies, Research Institute for the Languages of Finland (RILF), Special Libraries

Association (SLA), and United Nations Group of Experts on Geographical Names (UNGEGN).

The Unicode Consortium and ISO 15924

International Standard ISO 15924, *Information and Documentation—Codes for the Representation of Names of Scripts* was developed by the ISO technical committee TC 46 (Information and documentation) following on earlier work by ISO/TC 37 (Terminology and other language and content resources).^[28] The script codes created under the provisions of ISO 15924 are “devised for use in terminology, lexicography, bibliography, and linguistics, but they may be used for any application requiring the expression of scripts in coded form.”

ISO appointed the Unicode Consortium as the Registration Authority for ISO 15924.^[29] The Registration Authority is responsible for maintenance of the script codes, including evaluation of proposals for additional codes. It is advised by a Joint Advisory Committee (JAC); members of the JAC represent the Registration Authority and other relevant ISO technical committees and agencies.

UNICODE IN COMPUTERS AND ON THE WEB

Microsoft's Windows NT 3.1, released in 1993, was the first major operating system to support Unicode.^[30] Today, the Unicode Standard provides the foundation for an increasingly global information technology industry based on the World Wide Web and XML (Extensible Markup Language).

The World Wide Web Consortium (W3C) has developed two syntaxes for Web documents—HTML (Hypertext Markup Language) and XML—both of which allow use of Unicode. *Unicode in XML and Other Markup Languages* has been published jointly by W3C and the Unicode Consortium.^[31]

HTML allows use of various character sets, including Unicode (as its International Standard counterpart, ISO/IEC 10646). Unicode was adopted as the document character set for HTML in HTML 4.01.^[32] Specifically, section 5.1 *The Document Character Set* states: “The ASCII character set is not sufficient for a global information system such as the Web, so HTML uses the much more complete character set called the *Universal Character Set* (UCS), defined in [ISO10646]. This standard defines a repertoire of thousands of characters used by communities all over the world.” and “The character set defined in [ISO10646] is character-by-character equivalent to Unicode ([UNICODE]).”

XML, developed initially for electronic publishing, is increasingly used for data storage and exchange.^[33] Unicode is XML's default character set. In *Extensible Markup Language (XML) 1.0*, Section 2.2 “Characters”

states: “Legal characters are tab, carriage return, line feed, and the legal characters of Unicode and ISO/IEC 10646.” Section 4.3.3 “Character Encoding in Entities” requires “All XML processors MUST accept the UTF-8 and UTF-16 encodings of Unicode 3.1.”

The *Character Model for the World Wide Web 1.0: Fundamentals*, approved as a W3C Recommendation in 2005, provides “a common reference for consistent, interoperable text manipulation on the World Wide Web” and builds on “the Universal Character Set, defined jointly by the Unicode Standard and ISO/IEC 10646.”^[2] It discusses the concepts *character*, *encoding*, and *string*, as well as processing issues such as string indexing.

The *Character Model for the World Wide Web 1.0: Normalization* is currently at the Working Draft stage.^[34] The *Character Model for the World Wide Web 1.0: Resource Identifiers*, currently at the W3C Candidate Recommendation stage, addresses character encoding of resource identifiers, “a compact string of characters for identifying an abstract or physical resource.”^[35]

UNICODE AND LIBRARIES

In libraries, the predominant interest in Unicode has been its potential to improve access to material written in non-Latin scripts that were not covered by MARC 21 or UNIMARC, but this is only one of the benefits of using Unicode for library data.

The overall benefit is that use of Unicode eliminates the isolation of libraries from mainstream information technology. Because Unicode supports the needs of all types of users, including libraries, there is no longer any need for library-specific character sets. All modern software and protocols utilize Unicode, so commercially available software and fonts can be more easily used in library applications.

In 2007, the MARC 21 specifications were amended to remove the restriction permitting use of only a subset of Unicode characters.^[36] A much-desired benefit of this amendment is the ability to include additional non-Latin scripts in MARC 21 exchange records.

For scripts that have always been permitted in MARC 21 records, the benefit of this change is that additional elements of text may now be transcribed directly, instead of being represented via a cataloging convention (such as a description enclosed in brackets) or in romanization. Examples of characters that may now be used in MARC 21 records include

- For Latin script, additional letters include those such as *B with hook*, needed to write certain African languages, and the letters *yogh* and *wynn* of archaic English.
- Five times as many East Asian ideographs in the Unicode Standard as in EACC: over 70,000 compared

to over 13,000.^[37,10] National and industry character sets of East Asia were important sources for the ideographic content of Unicode.

- An extensive repertoire of mathematical, technical, and musical symbols.

Libraries are making increasing use of general information technology standards, XML in particular. Because Unicode is fundamental to modern information technology, new protocols and products for libraries are making increasing use of Unicode, if only through using a particular methodology that, in turn, relies on Unicode. Unicode is specified as the default character set of XML, so a library application based on XML uses Unicode, unless an alternative encoding is explicitly declared.

The remainder of this section discusses use of Unicode in those library technology specifications that originated before HTML and XML were available: MARC 21, UNIMARC, and Z39.50.

Unicode and MARC 21

Prior to the development of the Unicode Standard, MARC 21 specified 12 individual character sets, (sometimes referred to as “MARC-8” because of their use in an 8-bit environment).^[38] Five of the character sets—Basic Latin (equivalent to ASCII), Extended Latin (a superset of ANSEL), superscripts, subscripts, and Greek symbols—were used in records in any of the MARC 21 formats.^[22,12] The other seven—Basic Hebrew, Basic Cyrillic, Extended Cyrillic, Basic Arabic, Extended Arabic, Greek, and EACC—were used only in bibliographic records.

For records encoded with the MARC-8 character sets, the default character sets are Basic Latin and Extended Latin.^[39,11] In many systems used by libraries, the five character sets common to all MARC 21 records were implemented as a single “Latin” or “Roman” character set.

Use of Unicode in MARC 21 records was approved in 1998 with acceptance of MARBI Proposal 98-18.^[40] MARC 21 records must be encoded either in the Unicode encoding form UTF-8 or in the older individual character sets. The Library of Congress has published mappings from the characters of the individual MARC 21 character sets to Unicode equivalents (expressed as UTF-8 byte sequences).^[41] Initial use of Unicode in MARC 21 records was limited use to a specified subset of writing systems, corresponding to the scope of the individual MARC 21 character sets; the restriction was lifted in 2007.^[36]

Use of Unicode in MARC 21 affects the order of combining characters relative to the base letter. (*Combining characters* is the term used in MARC 21 documentation for what are called *diacritics*, *non-spacing graphic characters* or *character modifiers* in other library contexts.) With the introduction of Unicode as an encoding option

for MARC 21 exchange records, the position of the base letter relative to combining characters now depends on the encoding being used. When data is encoded in UTF-8, the Unicode convention of base letter first is followed. When data is encoded in the MARC 21 character sets, the original MARC convention of base letter after the combining character(s) applies.

In 2007, the Library of Congress announced that non-Latin characters were to be allowed in references in name authority records.^[42] Initially, the character content of the records is limited to the repertoire of the MARC-8 character sets. Authority records exchanged between NACO nodes are encoded in UTF-8. (NACO is the Name Authority Cooperative Program of the Program for Cooperative Cataloging.) Cataloging Distribution Service subscribers may choose MARC 21 authority records in either UTF-8 or the MARC-8 character sets.

Because some older library systems may still be limited to the individual MARC-8 character sets, two methods have been defined for representation of Unicode characters that cannot be mapped to any of the characters in these sets.^[43] One method, which substitutes the vertical bar character (ASCII hexadecimal 7C) as a placeholder for the unmappable character, is *lossy*, that is, destructive because the identity of the unmappable character is lost. The alternative method is *lossless* because the character that could not be converted is explicitly identified by a numeric character reference (NCR), modeled on character entity references in HTML.

Unicode and UNIMARC

UNIMARC, published by the International Federation of Library Associations and Institutions (IFLA) is the other international exchange format for MARC records.^[8] Manuals have been published for the bibliographic, authorities, and holdings formats; the classification format is under development.

Like MARC 21, UNIMARC specifies use of individual character sets, nine published by ISO, and one (Basic Cyrillic) registered with ISO. When individual character sets are used in a UNIMARC record, the default character set is ISO/IEC 646, the International Reference Version (IRV) of ASCII.^[23]

UNIMARC also specifies “ISO 10646 Level 3 (Unicode, UTF-8)” as a valid character set. No other character sets are used in this case. “Level 3” is a feature of ISO/IEC 10646 to designate data that may include combining characters.

A unique feature of UNIMARC is the ability to include coded information about use of scripts in a record. UNIMARC specifies 16 two-letter codes, rather than using the codes defined in ISO 15924.^[28] Additional codes indicate the reading direction of the script; left to right, or right to left. These script and direction codes are used in

the *General Processing Data* field (tag 100) and in subfield 7 that conveys script information for specific fields.

Unicode and Z39.50

Z39.50 is the original cross-system search and retrieve protocol developed for library use.^[44] Version 3 was updated in April 2002 to add the “10,646 character set” to the character set choices for character set and language negotiation.^[45] Supplementary choices cover *collection*, *implementation level*, and *syntax*.

Using this terminology derived from International Standard ISO/IEC 10646, Unicode data has these features: collection designation to identify which version of the Unicode Standard is used, implementation level 3, and one of the syntax choices UTF-8, UTF-16, and UCS-4 (=UTF-32).^[46]

LIBRARY SYSTEMS

Surveys conducted in 2002 and 2006 of providers of library systems and services showed that most integrated library systems already utilized Unicode internally to some extent.^[47,48] The earlier study by Tull identified two record storage situations: use of UTF-8, and storage in the MARC-8 character sets with conversion to UTF-8 for browser display. With the removal of the restriction on data content of MARC 21 records in 2007, any integrated library system that does not utilize Unicode end-to-end will soon do so.

The MARC 21 restriction applied only to the exchange of data. Some libraries and organizations began to use additional scripts within their own system before the restriction was removed e.g., OCLC introduced support for Tamil and Thai in 2006; Bengali and Devanagari were subsequently added.^[49,50]

Changes to the MARC 21 formats (e.g., the changes related to Unicode use introduced in 2007) are not always implemented in library software products. The ALCTS (Association for Library Collections and Technical Services) Task Force on Non-English Access received comments pointing out that products supporting interlibrary loan, bibliographic citations, and federated searching do not support non-Latin script data adequately; the cause is undetermined.^[51,52]

CONCLUSION

The development of the Unicode Standard is one of the most significant events in information technology. Unicode is fundamental to the worldwide exchange and display of textual information in multiple languages and scripts. Its use is now well established in all types of systems, software, and standards.

In the library community, Unicode has been viewed as the solution to the lack of support for non-Latin scripts in library systems, but it is far more than that. Finally, libraries and the information industry are using the same method to encode data, which means that mainstream technology can be brought into libraries with considerably less effort. The enormous increase in the repertoire of available characters allows for more the accurate description of library resources. The need for romanization is greatly reduced, significantly improving access to library resources, particularly for those who use non-Latin writing systems. The Unicode Standard brings major benefits to libraries and their users worldwide.

Betsy L. Humphreys

National Library of Medicine, Bethesda, Maryland, U.S.A.

Abstract

The Unified Medical Language System (UMLS) is a long-term research and development effort of the National Library of Medicine, aimed at assisting users in finding information from multiple sources without understanding the intricacies of each particular source. Consisting of three major knowledge sources, a Metathesaurus, a Semantic Network, and a set of lexical processing tools, the UMLS is produced and released twice yearly. Recent efforts have been aimed at expanding coverage in genetics and in clinical vocabularies designed for use in medical record systems. RxNorm, produced and released on a monthly basis, with weekly updates, is an outgrowth of the UMLS, focusing on medication terminology.

INTRODUCTION

In 1986, Donald A. B. Lindberg, M.D., Director of the National Library of Medicine (NLM), initiated a long-term research and development effort known as the Unified Medical Language System. Anticipating increasing amounts of biomedical information available in electronic form, he believed that NLM should facilitate the development of advanced information systems that could retrieve and integrate information from a variety of disparate information sources, including bibliographic databases, patient record systems, factual databanks, and knowledge bases. He recognized that a major barrier to effective retrieval and integration of information from multiple sources was the “naming problem,” the variety of different ways that the same concepts are expressed in different information sources and by different information seekers.

To address the complex problems of relating user inquiries to the content of biomedical information sources and of aggregating comparable data derived from disparate databases, the NLM assembled a multidisciplinary in-house research group and also awarded a series of research contracts to a number of primarily academic investigators. The first several years of UMLS research were devoted to studying user needs, developing research tools, identifying required capabilities, exploring alternative methods for delivering these capabilities, and defining in general terms the new knowledge sources that would be needed to support integrated use of information from disparate electronic biomedical sources. Based on the results of this early work, the conception of UMLS components as “middleware” designed for use by system developers emerged. Rather than build a single vocabulary based on classical approaches, a methodology of integrating the disparate terminologies was designed. Since 1990, NLM

has issued regular editions of UMLS Knowledge Sources and associated lexical programs, at least annually. The current frequency of releases is two times per year.

Over the past 18 years, the UMLS resources have grown and developed, the methodology for creating them has matured, and their utility has been demonstrated in many different information systems. Today more than 3000 individuals and institutions worldwide license the UMLS resources, which are free-of-charge. The majority of the licensees use one or more of the UMLS components in information systems, often in creative and innovative undertakings. The NLM itself uses UMLS components to enhance retrieval from a number of its information services, including the MEDLINE database available via PubMed, the ClinicalTrials.gov database of ongoing clinical trials sponsored by the National Institutes of Health and other organizations, and the NLM Gateway, which provides a single point of entry to a number of different NLM databases. The Library also relies heavily on the UMLS resources to aid its high volume indexing and cataloging operations and in its natural language processing and digital library research programs.

Subsequent sections of this entry describe: 1) UMLS Knowledge Sources in general, 2) key characteristics of the Metathesaurus and the Semantic Network, 3) the production of the Metathesaurus and the distribution mechanisms for the UMLS resources, 4) MetamorphoSys, a utility program that assists UMLS users in unpacking new releases and customizing the Metathesaurus for particular applications, and 5) RxNorm, a standardized nomenclature for clinical drugs, that addresses special requirements for linking medication vocabularies that were not amenable to Metathesaurus construction techniques.

THE KNOWLEDGE SOURCES

There are three major UMLS knowledge sources: a large Metathesaurus® of concepts and terms from many biomedical vocabularies and classifications; a Semantic Network of sensible relationships among the broad semantic types or categories to which all Metathesaurus concepts are assigned; and the SPECIALIST Lexicon which contains syntactic, morphological, and orthographic information for biomedical and common words in the English language. The Lexicon and its associated lexical resources are used to generate the indexes to the Metathesaurus and also have wide applicability in natural language processing applications in the biomedical domain. From 1991 to 1998, the NLM also produced a fourth UMLS Knowledge Source, an Information Sources Map that described the scope, content, and access conditions for many publicly available biomedical databases. The development of the World Wide Web offered other promising approaches to addressing the problem of determining which of many information sources contain content relevant to a particular inquiry.

The Metathesaurus and the Semantic Network will be discussed in this entry. Those interested in the SPECIALIST lexicon and its related natural language processing resources should consult the Bibliography at the end of this entry.

The Metathesaurus

The Metathesaurus is the central vocabulary component of the UMLS. The term Metathesaurus draws on Webster's Dictionary third definition for the prefix "Meta," i.e., "more comprehensive, transcending." In a sense, the Metathesaurus transcends the specific vocabularies and classifications it encompasses.

The Metathesaurus is a database of information on concepts whose names appear in one or more of a number of different controlled vocabularies and classifications used in the field of biomedicine. In general, the scope of the Metathesaurus is determined by the combined scope of its source vocabularies. The Metathesaurus preserves the meanings, hierarchical connections, and other relationships between terms present in its source vocabularies, while adding certain basic information about each of its concepts and establishing new relationships between concepts and terms from different source vocabularies.

The Metathesaurus contains concepts and concept names from more than 145 vocabularies and classifications, some in multiple editions. The April 2008 release of the Metathesaurus (2008AA) includes approximately 1.55 million concepts and 7.78 million concept names. Most of the source vocabularies are included in their entirety. Some material from the UMLS Metathesaurus is from copyrighted sources.

Of particular note are two collections of source vocabularies relating to important areas in modern biomedicine. The inclusion of major genomics vocabularies—the Gene Ontology, the Human Genome Organization (HUGO) Gene Nomenclature, and the names of clinical genetic syndromes from Online Mendelian Inheritance of Man (OMIM)—makes the UMLS Metathesaurus a useful tool in mining the genomics literature for data and in linking genomic and clinical information together.

The UMLS Metathesaurus also includes standard vocabularies believed useful in building, indexing, and aggregating electronic health records and in enabling sophisticated clinical decision support at the point of care. As the central coordinating body for standard clinical terminologies within the Department of Health and Human Services, NLM plays a leading role in making key clinical terminologies freely available within the United States and in mapping them to administrative coding systems, used in health statistics and health care billing. Since 1999, NLM has funded the ongoing development and free dissemination of Logical Observations Identifiers Names and Codes (LOINC), a standard nomenclature for laboratory tests and other clinical measurements. In 2003, the Library negotiated an innovative U.S.-wide license for the Systematized Nomenclature of Medicine—Clinical Terms (SNOMED CT) to make this vocabulary available for U.S.-wide use. NLM also assisted the formation of the International Health Terminology Standards Development Organisation, which purchased SNOMED CT from the College of American Pathologists in 2007. NLM is the U.S. member of this new international organization. The Library itself produces the RxNorm clinical drug terminology (see below). The UMLS Metathesaurus is one of the dissemination vehicles for these standard clinical terminologies and for the mappings from them to administrative classification and coding systems, such as the International Classification of Diseases, Current Procedural Terminology, and the Healthcare Common Procedure Coding System.

Organization of the Metathesaurus

I. A. Richards, in his introduction to Roget's Pocket Thesaurus, described a thesaurus as the opposite of a dictionary, where you go to look up a word when you know the meaning. By this definition, a thesaurus is organized by the principle of semantic locality. That is, words and phrases close to one another in meaning can be found in the same area. A review of the first thesaurus in the English language, which was designed by Roget, illustrates that principle. Organized in general categories, then into more specific ones, are lists of words and phrases close in meaning to one another.

The Metathesaurus is organized according to this broad principle. All words and phrases that mean the same thing form a distinct concept or synonym class in the

Metathesaurus. Each separate meaning appears as its own concept, together with links (represented relationships) to other concepts in the Metathesaurus. These relationships to the other concepts serve to define the semantic neighborhood of the concept. A user of the Metathesaurus, whether human or program, can navigate within this semantic neighborhood to find the names for the concept sought.

Multiple meanings of the same term are dealt with by separating the meanings and presenting them in different semantic neighborhoods. If you look up the word “tree” in a dictionary you will see one entry with multiple definitions. If you search for “tree” in the Metathesaurus you will find that it names two separate concepts. One concept is the plant and the other one means hierarchy. Each of these meanings has differing relationships within the Metathesaurus.

Although the Metathesaurus can be usefully compared with Roget’s thesaurus, it does not fit the common information science definition of “thesaurus” as a list of preferred subject headings or descriptors, often with a cross-reference structure, created for use in the organization and retrieval of documents within some domain. This definition of thesaurus applies to some of the source vocabularies within the Metathesaurus, but not to the Metathesaurus itself, which necessarily encompasses vocabularies with a wide range of different purposes and semantic and structural properties.

Concept structure

The first step in organizing the Metathesaurus is to connect the alternative names for the same concept. Each concept record contains the strings of alphanumeric characters and terms that express the meaning of the concept. Strings that are lexical variants of each other (that is, identical after a series of well-defined manipulations that can be done computationally, e.g., making all characters lower case, putting all words in a defined order, and changing all plural forms to singular) are grouped together as a single term. One string is designated, by convention, as the preferred form of that term. Table 1 illustrates the terms for one meaning of, “Milk Hypersensitivity.” In Table 1, “Milk Hypersensitivity” and “Hypersensitivity, Milk” are lexical variants. Also in Table 1, the ten terms all have the same meaning. They are therefore linked together as alternate names of the same concept, with one term designated as the preferred name of the concept. The designation of preferred forms and preferred names is done by algorithm based on an order of precedence among source vocabularies. Because this is done by an arbitrary convention, any user can change and select their own order of precedence among vocabularies using their own tools or MetamorphoSys (see below).

Each concept in the Metathesaurus has a unique concept identifier (CUI), which itself has no intrinsic

Table 1 Synonymous terms and their sources.

Source: Material drawn from the 2008 UMLS Metathesaurus.

meaning. This unique identifier is represented in the Metathesaurus by the letter C followed by one or more digits (i.e., C0010028). This identifier remains the same across versions of the Metathesaurus, irrespective of the term designated as the preferred name of the concept. This facilitates file maintenance and management, as well as tracking the meanings assigned to a given term changes over time. It is “the name [of a concept] that never changes.”

Relationships

The Metathesaurus also represents relationships between different concepts. Many relationships are derived directly from the source vocabularies. For example, the fact that there is a relationship between “Opium” and “Plant Extracts” is derived from the hierarchical tree structures in the Medical Subject Headings (MeSH) vocabulary. The exact nature of the relationship may or may not be represented in the source vocabulary, although the contextual and hierarchical relationships are identified as such. Relationships between concepts from different source

Table 2 Relationships within the UMLS Metathesaurus.

Relationship	Definition
Broader (RB)	Has a meaning which includes that of the concept.
Narrower (RN)	Has a meaning which is included in that of the concept.
Other related (RO)	Has a relationship other than synonymous, narrower, or broader.
LIKE (RL)	The two concepts are similar or “alike.” In the current edition of the Metathesaurus, most relationships with this attribute link MeSH supplementary concepts which are largely chemicals. Many of the concepts linked by this relationship may be synonymous and will be in a single concept identifier in future editions of the Metathesaurus. Source-specific mappings from one vocabulary to another also have this relationship, along with the label for the relationship attribute of “mapped_to.”
Parent (PAR)	Is a parent in a hierarchy of a Metathesaurus source vocabulary.
Child (CHD)	Is a child in a hierarchy of a Metathesaurus source vocabulary.
Sibling (SIB)	Shares a parent in a hierarchy in a Metathesaurus source vocabulary.
AQ	Is an allowed qualifier for a concept in a Metathesaurus source vocabulary.
QB	Can be qualified by a concept in a Metathesaurus source vocabulary.

vocabularies are also, on occasion, created during Metathesaurus construction. For example, the MediSpan (MDDb) concept “Infant Foods Powder” is identified in the Metathesaurus as having a narrower-than relationship to “Infant Food,” a concept that is present in MeSH, SNOMED, and others.

Nine types of relationships exist in the Metathesaurus. They are listed in Table 2. Relationships are reciprocal, so that, for example, where one concept is broader than another, the other is noted as being narrower than the first. Relationship attributes, describing the exact nature of a relationship, may be assigned to a given relationship. These attributes include the set of permissible relationships within the Semantic Network (discussed below), with additional relationships, including that of “mapped_to.” Other relationship attributes originate from the source vocabularies.

Many of the source vocabularies included in the Metathesaurus place the concepts they include in some context. These contexts are in general hierarchical arrangements, for some organizational or classification purpose. NLM endeavors to preserve all of these different contexts in the Metathesaurus, so a single concept in the Metathesaurus can appear in multiple different hierarchies. As an example, several of the contexts in which the concept “fruit” appears are shown in Table 3. There is no

attempt to merge or combine the different contextual views into one coherent hierarchical arrangement for the Metathesaurus. Given the different perspectives and purposes of the many UMLS source vocabularies, this would be an essentially impossible task.

Semantic types

Each Metathesaurus concept is assigned at least one semantic type. The types are drawn from the Semantic Network (see below). The types provide a general categorization of the concept, and allow some reasoning about the possible meaning of the concept. In all cases, the most specific semantic type available in the hierarchy is assigned to the concept. For example, the concept “Macaca” receives the semantic type “Mammal” because there is not a more specific type, e.g., “Primate,” available in the Network.

Additional attributes

Within each concept, there are many data elements provided both by the sources and created by NLM. There are over 110 attributes and data elements in the Metathesaurus. Each attribute in the Metathesaurus is labeled with the source, which asserted that attribute.

Of particular note is that there may be narrative description(s) of the meaning of the concept. The majority of these definitions come from MeSH and National Cancer Institute (NCI) Thesaurus, but there are also definitions from a number of other sources. A few definitions are created specifically for the Metathesaurus when they are needed to distinguish among different meanings of the same string.

The Semantic Network

The Semantic Network is tied very closely to the content of the Metathesaurus. In general, semantic networks attempt to impart common sense knowledge to computers, allowing them to “reason” and draw conclusions about entities by virtue of the categories to which they have been assigned. The semantic links provide the structure for the network and represent important relationships in the domain. The UMLS Semantic Network consists of 135 semantic types, broad categories intended to indicate the general area of meaning of a Metathesaurus concept, together with 54 relationships or semantic links.

The Semantic Network can be visualized as a diagram where the types make up nodes within a network. The top of the network has two nodes, “Entity” and “Event.” The remaining types each appear only in one location within the network. Figure 1 includes a portion of the UMLS Semantic Network.

The primary link between the nodes is the “isa” link. This establishes the hierarchy of types within the Network

and is used for deciding on the most specific semantic type available for assignment to a Metathesaurus concept. In addition, a set of nonhierarchical relations between the types has been identified. These are grouped into five major categories, which are themselves relations: “physically related to,” “spatially related to,” “temporally related to,” “functionally related to,” and “conceptually related to.”

The relations are stated between semantic types and do not necessarily apply to all instances of concepts that have been assigned to those semantic types. That is, the relation may or may not hold between any particular pair of concepts. So, although “treats” is one of several valid relations between the semantic types “Pharmacologic Substance” and “Disease or Syndrome,” a particular pharmacologic substance (e.g., penicillin) may not treat a particular disease (e.g., AIDS).

PRODUCTION AND DISTRIBUTION OF THE UMLS

Making the Metathesaurus

To understand the process of making the Metathesaurus, it is helpful to review the steps taken in adding a new vocabulary to the Metathesaurus. (Adding an update to a vocabulary already present in the Metathesaurus is quite similar.) The NLM begins by acquiring the rights to incorporate a vocabulary into the Metathesaurus. The rights include permission to include and represent the vocabulary in this form, and to distribute the vocabulary to UMLS licensees. However, a UMLS license alone does not permit a licensee to use every source vocabulary for any purpose. For some applications of some source vocabularies, the user must also establish a separate agreement with the individual vocabulary producer. The UMLS license describes when this is necessary.

Once a machine-readable version of a vocabulary is made available to the NLM it is converted into a “normal” or canonical form. This “inversion” process requires careful consideration of how the source represents its meanings and attempts to make all of this representation explicit. Depending on the vocabulary and the context of

a given term, the meaning of that term, what is being named by it, can differ from the same term in other vocabularies. Each source is then added to the existing Metathesaurus. Terms from different sources which are lexically similar to each other or to existing terms in the Metathesaurus, or which appear from other indications to be semantically identical to concepts in the Metathesaurus, are brought together (merged) as proposed synonyms located in a single Metathesaurus concept.

After this merging, the results are reviewed by editors, largely to assess if the proposed concept merge is appropriate. This human step, which requires understanding of the meaning of a term in the source is the key to successful linking of that term to different terms from different source vocabularies. Contextual information about what is being named can be almost entirely implicit (e.g., a vocabulary describing medical procedures with a drug term name may really mean the procedure of administering that drug), or represented more explicitly. Judging whether or not the same referent is being named can be difficult. Practical decisions of what constitutes synonymy are dominated by the consideration of what an expert in the area might discern as a notable difference in meaning. Editors also may add information such as additional relationships and semantic types. This human review is expedited by computational assistance, as is the quality assurance that takes place after the editing.

In categorizing the concepts, editors are encouraged to consider the most specific semantic type available. If the concept is broad or not represented by a more specific type, a broad category in the semantic type hierarchy is used. For example, a sub-tree under the node “Physical Object” is “Manufactured Object.” It has three nodes, “Medical Device,” “Drug Delivery Device,” and “Research Device.” It is clear that there are manufactured objects other than medical devices, drug delivery devices, or research devices. Rather than proliferate the number of semantic types to encompass multiple additional

subcategories for these objects, concepts that are neither medical devices nor research devices are simply assigned the more general semantic type “Manufactured Object.”

Periodically various types of quality assurance efforts are performed. The most important of these are efforts to ensure that there is no missed synonymy, i.e., no terms meaning exactly the same thing in different concepts. Another important effort is made to ensure that every concept is linked to others by some relationship.

In preparation for releasing of the next version of the Metathesaurus, all new releasable concepts are assigned CUIs, while concepts previously present in the Metathesaurus retain their CUIs. The Metathesaurus is released as a set of relational tables. Each term in a source is identified with its own unique identifier, and a group of terms judged synonymous share the same CUI.

Licensing and Distribution of the UMLS

The UMLS is available free of charge to anyone who wishes to license it. The license agreement, available at <http://www.nlm.nih.gov/research/umls/>, must be completed and signed electronically. As noted above, UMLS licensees may also have to enter into separate license agreements with the producers of specific vocabularies present in the Metathesaurus. No additional agreements are required for use of the other UMLS components.

Licensed users may ftp the UMLS Knowledge Sources or access them interactively from the UMLS Knowledge Source Server. On request, DVDs are provided to users who do not have adequate connectivity to ftp the large files.

MetamorphoSys

As the Metathesaurus has grown in size, dealing with the file sizes and the many constituent vocabularies has introduced new challenges, requiring custom compression

techniques for the packaging and distribution of the content. This has consequently created the need for a tool to allow users to unpack the data at their local installations. Furthermore, due to the different needs of the users, the entire content of the Metathesaurus is rarely needed or wanted for any specific application. Some content may actually be harmful to particular applications, or users may not have the additional licenses required for some uses of some source vocabularies. Thus, the need arises to create useful, user-definable subsets of the Metathesaurus with all the data and referential integrities present in the full release. This, in general, is a nontrivial task beyond the scope of many users.

MetamorphoSys is a utility program designed to meet these and other needs. An early version for subsetting was first introduced in 1999 and has since then grown into its current form as an installation, subsetting, and browsing tool for the UMLS Metathesaurus. It is implemented as a platform-independent Java application freely distributed with the UMLS data on the DVD or available as an Internet download.

MetamorphoSys is first an installation program for the UMLS. It is required to unpack the UMLS knowledge sources from the internal, compressed distribution format. It allows customization on a variety of axes: inclusion/exclusion by source and term type, semantic type, language, content view, etc. It permits reorganizing the ranking precedence of the different sources that contribute meaning to concepts. Users can also modify the suppressibility of concept names that might not be useful, or even harmful, in their applications. It comes with input and output handlers for a variety of formats. It provides load scripts to allow the Metathesaurus and Semantic Network data for subsets to be loaded into a database management system. It is designed with an open, extensible architecture so users can define custom filters to include or exclude either whole concepts or constituent elements of concepts in predictable ways.

Included as part of MetamorphoSys is a browser application that can be used to browse the custom subsets of the Metathesaurus created. The browser can display reports for concepts searched for in a variety of ways: by concept unique identifier, by code, or by words in the concept names. Both the search and display can be constrained by source, semantic type, and content view. There is an integrated tree browser that allows users to navigate the hierarchies of all sources that provide contexts.

RxNorm

RxNorm is a standardized nomenclature for clinical drugs. RxNorm, and its associated contributing vocabularies, address an important issue in supporting interoperability that could not be addressed by the traditional means of building the Metathesaurus. Unlike other portions of the

Metathesaurus, RxNorm deals with the problem of unrecognized synonymy by establishing standard, normalized, names for the clinical drugs, defined as ingredients and strengths provided in a dosage form. Each drug has a name created using a standard methodology, with controlled segments, and with defined relationships to other concepts in RxNorm. The names are created by reviewing the names within one of the source vocabularies, and then using the information in that name and source to create the standard name, asserting synonymy between that source vocabulary name and the created name.

In response to the perceived need for frequent updates to clinical drug information, RxNorm provides monthly releases of all of its source vocabularies, together with the standard names created in the RxNorm system, with more frequent releases of new additions. The file formats are essentially identical to that of the Metathesaurus. Identifiers from the Metathesaurus are consistent with the identifiers in the current extant version of the Metathesaurus. At the time of release of the Metathesaurus, the next (usually simultaneous) release of RxNorm is consistent with the new release.

CONCLUSION

The NLM produces and distributes the UMLS, consisting of multipurpose, electronic Knowledge Sources and associated software tools for system developers and researchers in the fields of biomedicine and health. The unique characteristics, large scale, and regular update schedule of the UMLS resources have promoted their heavy use in wide range of information retrieval, natural language processing, data creation, and decision support applications.

Uniform Computer Information Transactions Act (UCITA)

Sarah K. Wiant

School of Law, Washington and Lee University, Lexington, Virginia, U.S.A.

Abstract

The Uniform Computer Information Transactions Act (UCITA) is an attempt to conform state law relating to software and information licensing to a uniform national standard. UCITA began as a proposed revision to the Uniform Commercial Code (UCC). For more than 10 years the National Conference of Commissioners on Uniform State Laws (NCCUSL) and the American Law Institute (ALI) debated the merits of various proposals to cover the licensing of software and information, including the proposal UCC 2B, but were unable to agree on a solution. In May 1999, the ALI withdrew its support after concluding that the UCC 2B approach was flawed. Despite opposition from the ALI and dozens of educational, library, and consumer groups, NCCUSL ratified the model legislation in July of 1999, renamed it UCITA, and sent it to the states for enactment without either the endorsement of the ALI or a review by the American Bar Association. UCITA enjoys strong support among the high-technology community including large software companies like Microsoft and Internet companies like AOL. UCITA has also met with stiff opposition throughout its 10 years history. Critics have expressed concerns about its wide-reaching scope, its effect on existing copyright and consumer protection laws, and its questionable fit with the First Amendment. These and other issues, such as its favorable treatment of choice of law and forum clauses and the difficulty of meeting its standard of unconscionability, have resulted in its failure to gain acceptance in most states. Courts are still trying to resolve many of these issues today. The overall trend appears to be toward enforcement of shrink-wrap license agreements when the licensee has an opportunity to review the terms and accept or reject them. Thus, in spite of NCCUSL's failure to gain wide acceptance of UCITA, decisions by the courts could ultimately have a similar impact on the way information transactions are viewed.

INTRODUCTION

The Uniform Computer Information Transactions Act (UCITA) is an attempt to conform state law relating to software and information licensing to a uniform national standard. Specifically, the legislation was drafted to address the problem of “shrink-wrap” software licenses, which bind consumers to their tenets as a condition of use. Often this term generically encompasses “click-through,” “active click wrap,” and “browse-wrap” licenses, which accompany much of the information found online. Unlike shrink-wrap licenses, which take their name from the plastic they are often printed on, click-through, active click wrap, and browse-wrap licenses exist only electronically. They typically appear on the monitor as a condition of accessing information or installing software. Most users agree to these conditions as a matter of course, without stopping to read or consider their restrictions. Although licenses such as these have become commonplace, some courts have hesitated to enforce them. Disparate judicial treatment of these agreements led to an attempt to standardize the law relating to them.

HISTORY

UCITA^[1] began as a proposed revision to the Uniform Commercial Code (UCC). Most states have adopted the UCC or some version of it, and it is generally considered the most influential source of contract law in the United States. It is drafted by two groups, the American Law Institute (ALI)^[2] composed of some 3000 elected judges, law professors, and lawyers and the National Conference of Commissioners on Uniform State Laws (NCCUSL),^[3] an organization comprised of approximately 300 lawyers, judges, and law professors appointed by states as commissioners. If both organizations approve a revision, it is then generally reviewed by the American Bar Association (ABA) before being submitted to each state government for adoption. Each state then enacts the proposed section or selected provisions, and those enactments become the law of that state.

For more than 10 years the two groups debated the merits of various proposals to cover the licensing of software and information, including the proposal UCC 2B, but were unable to agree on a solution. Current law is based on transactions of tangible goods. Both sides saw a need for

consistent and clear uniform rules for transactions involving software and information. In May 1999, the ALI withdrew its support after concluding that the UCC 2B approach was flawed.^[4] Despite opposition from the ALI and dozens of educational, library, and consumer groups, NCCUSL ratified the model legislation in July of 1999, renamed it UCITA, and sent it to the states for enactment without either the endorsement of the ALI or a review by the ABA.

The model legislation has been studied by or introduced to at least 27 state legislatures, but only Virginia and Maryland have enacted it. Although Virginia, in 2000, was first to enact this legislation, a compromise was struck by the General Assembly that delayed the effective date of UCITA in Virginia until July 1, 2001, allowing for a year of study and amendment.^[5] Maryland, the only other state to enact this legislation, set an effective date of October 1, 2000.^[6]

UCITA enjoys strong support among the high-technology community including large software companies like Microsoft and Internet companies like AOL. They support a free market where the parties choose models that support their transactions. It is opposed, however, by diverse groups, such as the Americans for Fair Electronic Commerce (AFFECT) which includes a coalition of library associations, newspaper and magazine publishers, insurance companies, and small engineering and software companies.^[7] A number of state Attorneys General signed a letter to NCCUSL expressing reservations about the proposed legislation.^[8]

Because of the controversial nature of the model legislation and the hearings and debates by numerous states, the matter was brought to the ABA. At its 2001 annual meeting, the ABA appointed a task force comprised of representatives from both sides of the debate to study further UCITA. On January 31, 2002, the ABA published a report of its findings on UCITA.^[9] Although the ABA acknowledged that UCITA is a worthy goal, and some measure of uniform regulations are needed for computer transactions, the ABA believed UCITA to be inadequate and too convoluted.^[10] NCCUSL responded with several amendments in 2002, however, these amendments failed to adopt some key ABA recommendations, including a requirement for pretransaction disclosure of terms.^[11] Anticipating rejection of these amendments, in February 2003 NCCUSL withdrew its resolution before it was voted on by the ABA House of Delegates.^[12] Without ABA support, in August of 2003 NCCUSL discharged the UCITA Standby Committee and announced that no further resources would be expended to promote UCITA.^[13] The debate has been spirited on both sides.

UCITA CONCERNS

UCITA has met with stiff opposition throughout its 10 years history. Critics have expressed concerns about its wide-

reaching scope, its effect on existing copyright and consumer protection laws, and its questionable fit with the First Amendment. These and other issues, such as its favorable treatment of choice of law and forum clauses and the difficulty of meeting its standard of unconscionability, have resulted in its failure to gain acceptance in most states. Courts are still trying to resolve many of these issues today.

Scope

This controversial legislation would have a profound effect on library operations because the definitions of information and computer information in UCITA cover just about everything. Information is defined as "data, text, images, sounds, mask works or computer programs, including collections and compilations of them."^[14] Computer information is defined as information in an electronic form which is obtained from or through the use of a computer or which is in a form capable of being processed by a computer. The term includes a copy of the information and any documentation package associated with the copy.^[15] These definitions include most information a library acquires, although UCITA excludes traditional written forms such as books. Only software and information in electronic format is covered, so a book on CD-ROM would be covered.

Two types of licenses are considered: mass-market licenses and specific one-on-one licenses. Mass-market licenses are those such as general retail or consumer licenses. They are nonnegotiated licenses. The specific one-on-one contracts are usually aimed at industry and are also covered. UCITA is the default when contracts are nonnegotiated or fail to address an issue. A UCITA license could allow content providers to bypass many of the protections traditionally afforded by the public law of copyright, and will likely replace it with the private law of contracts, becoming the central body of law governing information transactions. It gives greater power to copyright holders to write agreements restricting the use of their products.

Copyright and Software Licenses

Public policy

The Copyright Act of 1976 struck a careful balance, granting protection to authors in exchange for certain public uses of their works.^[16] Authors and other content providers are enabled by UCITA to contract around the important public uses guaranteed by copyright law. The statute would validate shrink-wrap and click-through licenses that would restrict uses by libraries allowed by federal copyright law. Libraries most rely on the following sections of the Copyright Act to carry on their day-to-day activities: section 109 of the Copyright Act establishes the

first sale doctrine as a result of which libraries can lend, sell, or otherwise distribute materials they have purchased; section 107 permits fair use on which libraries rely to make and distribute certain copies; and, section 108—the exemptions for libraries and archives—provides for preservation, lending, and interlibrary loan.

The first sale doctrine, set out in section 109 of the Copyright Act of 1976, terminates the rights of the author in the work after its initial sale, and allows the new owner, such as a library, to resell, dispose of, display, and make use of newly purchased content. Many functions, such as lending, browsing, and resale are triggered by the first sale of the work. More specifically, section 109 permits a nonprofit library or a nonprofit educational institution to lend software for nonprofit purposes.^[17] Because UCITA allows authors and publishers to license their works instead of selling them, no sale occurs, and the protections afforded under the first sale doctrine never ripen. Critics of UCITA argue that it limits rights of users to sell or transfer licensed software effectively overturning the Copyright Act's first sale doctrine.

In the absence of a sale, the right to sell or transfer licensed information remains with the author or his designee. The author of the work may impose restrictions on lending or reselling the information. Additionally, licenses last only for a finite period, driving costs higher as libraries repeatedly pay for access to the same information. The archival function of libraries could be severely curtailed: the expiration of the license may terminate access to the information, and any right to make archival copies could be limited by the terms of the license.

Even core values such as fair use are threatened by UCITA. Shrink-wrap and click-through licenses allow vendors to condition access to information on acceptance of the terms of an agreement. To access information, end users may have to agree to not reproduce the material. The fair use exemption on which educators rely for classroom^[18] and reserve^[19] copying may be in jeopardy. Moreover, copying done by individuals for purposes allowed under fair use of the Copyright Act^[20] such as copying for research and criticism also may be limited by shrink-wrap and click-through licenses. Although fair use would remain a defense to any copyright claim, the publisher could prevail on any claim based on the contract, rendering the copyright defense moot.

Libraries and archives fear that clauses in a UCITA contract would allow vendors to dictate limitations on rights otherwise available to them to conduct business. For example, without negotiation, interlibrary loans could be prohibited and remote access to information by students, faculty, and researchers could be limited by license terms. Such limitations would be particularly aggravating when the supplemental information to a book is supplied on a CD that may be loaned under section 108 of the Copyright Act,^[21] but may not be loaned with its companion book under a clause pursuant to UCITA.^[22] A license

could also limit copying to preclude the copies allowed for preservation purposes or even backup.

The Copyright Act exemptions allow users and libraries to make copies under restricted conditions without seeking permission and/or without paying royalties. These limitations were carved out of the copyright holder's exclusive rights based on public policies to encourage creativity. State laws like UCITA supplement federal intellectual property laws and policies, but in many ways they may impose new business models. The issue is the extent to which federal preemption controls.

The relationship between preemption under the federal copyright act of a state law that is equivalent to a right granted under copyright law and state contract law, which varies the effect of section 301 of the Copyright Act, is unclear.^[23] The legal issues are extremely complicated and are unresolved. Section 105 of UCITA speaks of the relation to federal law and fundamental public policy:

§ 105 Relation to Federal Law; Fundamental Public Policy; Transactions Subject to Other State Law.

- (a) A provision of this [Act] which is preempted by federal law is unenforceable to the extent of the preemption.
- (b) If a term of a contract violates a fundamental public policy, the court may refuse to enforce the contract, enforce the remainder of the contract without the impermissible term, or limit the application of the impermissible term so as to avoid a result contrary to public policy, in each case to the extent that the interest in enforcement is clearly outweighed by a public policy against enforcement of the term. . . .^[24]

As written, UCITA provides that if a federal law invalidates a state contract law or contract term, federal law controls. Section 105(a) refers to preemption but no general preemption of contracting issues arises under the copyright law.^[25] The model legislation does not specify when federal preemption may occur. Under section 105 of UCITA a court may refuse to enforce a contract if it violates fundamental public policy.^[26]

The commentary accompanying UCITA addresses the complexity of the problem, however, it leaves the broader issue to be resolved by a different body.^[27] Courts may follow the analysis set out in the commentary but are not required to do so. A contract may, however, be unenforceable because of federal preemption based on public policy. The issue is whether courts will consider fair use a fundamental public policy.

Public policies attempt to balance competing interests and define the allocation of risks between parties to prevent undesirable results that occur due to unequal bargaining power and strengths between parties. For example, the copyright law gives a creator a limited exclusive right to control the work for a finite term of protection and an incentive to create it.^[28] Society gains the benefit

of using the work after the limitation expires and the work becomes part of the public domain. The public also gains restricted access during the term of protection through exemptions to the exclusive rights based on public policy. Public policies apply to everyone. In contrast, contract law often allows the contracting parties to circumvent the balance struck by public policies. This competing value is known as “freedom of contract.”^[29]

While there are circumstances in which contracting around a public policy results in a socially and economically desirable result, when the circumstance does not permit negotiation, such as with a standard form contract, it is of substantial concern. Transactions costs may be minimized, but the end result for the nondrafting party may be a waiver of rights. Licensing terms for mass-market retail or online information products such as those used by libraries can “limit access to and use of electronic materials, prohibit making copies of materials for archiving or preservation or prevent interlibrary loan, or prohibit the transfer or donation of electronic products.”^[30]

National library amendment

Library groups in opposition offered an amendment that would replace existing section 105(b) with proposed 105(b)(1) and (2). The proposed amendment would allow parties to contract around public policies in a negotiated contract, facilitating commerce in the way that the drafters of UCITA envisioned, but would prevent the drafting party from imposing overreaching licenses in a standard form contract that favor the drafter, thus maintaining the benefit of public policies when the licensee has virtually no negotiating power. In some instances, a party might be willing to give up fair use rights. The proposed language, however, would have limited the broader effect of standard form contracts that might severely limit the ability to cite, criticize, reverse engineer, or otherwise use these works to society’s benefit.^[31] The proposed amendment attempted to balance the laissez-faire drafters, who would permit a new business model to try anything, with a certainty of social benefits to protect weaker parties. Unfortunately, none of these proposed changes have been adopted.

Some authorities in attempting to redress the imbalance between the freedom of contract of private property rights and the public good uses of information propose strict scrutiny of socially questionable terms and offer a doctrine of “public-interest unconscionability.”^[32] Undoubtedly, the enforcement of negotiated contractual agreements is a “fundamental public policy.” The question is how to handle agreements that arise from standard form contracts of adhesion. One way is to respect the traditional balance of public/private interests; the other way is to submit standard form contracts to a high level of scrutiny proposed by the public-interest unconscionability doctrine.^[33]

Virginia libraries amendment

During the year of study between the enactment and the effective date of UCITA in Virginia, the Virginia Library Association, concerned that UCITA would preclude the lending of a CD-ROM of information, perhaps even the supplement to a companion book, persuaded the General Assembly to amend the legislation to allow nonprofit libraries and archives to lend tangible copies (CD-ROMs) under restrictive conditions.^[34] NCCUSL met with members of the library community in the hope that language could be negotiated to become an amendment to the model version of UCITA that could be submitted to other states.

The statute permits a qualified library or institution to make a tangible copy available to users for course reserves or ordinary lending, including interlibrary loan; to copy for archival and preservation purposes; and to make use of the copy for classroom purposes.^[35] The amendment applies to conduct that is “not otherwise unlawful or restricted under the Copyright Act...” This arguably includes any act undertaken by a library under fair use or any other exemption that allows libraries, archives, and nonprofit educational institutions to carry out their missions; all of these exemptions are restrictions under the Copyright Act. Next, the statute provides that the standard form contract covers the use of a tangible copy of information content to a licensee. The question is whether a user must first determine if the shrink-wrap or the click-through license is a standard form contract. The benefit of this exemption is surprisingly not limited to a nonprofit library or archive or a nonprofit educational institution. Initially, the drafts included a very restrictive definition of libraries that would not include museums or government agency or court libraries, but after much debate between NCCUSL representatives and members of the library community, a clause was added to clarify that the “terms nonprofit library, archive or educational institution have the same meaning as used in section 108, 109, 110 of the Copyright Act, 17 U.S.C. §§ 108, 109, and 110.”^[36]

Much of the library community viewed the Virginia amendment as too restrictive and withdrew their support as a national amendment.^[37] The Virginia Association of Law Libraries (VALL) had several problems with the language offered to libraries, but because of the concern that opposition might affect funding for public libraries and other institutions it remained neutral during the legislative session.^[38] VALL, in particular, objected to the amendment’s narrow application to only tangible copies obtained by libraries, such as CD-ROMs, at a time when publishers are moving away from tangible products towards the online environment. It does not apply to online databases or to other content distributed directly over the Internet, therefore, providing only a short-term benefit, if any.^[39] Worse, it could be read to restrict further rights that otherwise are available under copyright law. By

specifying which uses can be made of tangible copies, the statute could be read to prohibit all other uses.

The amendment permits the copyright holder to vary the terms of the license providing that the change in terms is conspicuous, that the library manifests assent to the changes, or that the library knew or had reason to know that the terms would follow when it ordered a copy.^[40] There are numerous problems with this part of the statute. There is no definition of conspicuous. Although authorities have debated manifestation of assent, there is generally no accepted definition for behavior that would constitute assent. Because staff, who may have little or no training in issues of intellectual property law, open most material received by libraries, by opening the package their behavior may constitute assent. Moreover, the software often must be loaded and run before the terms can even be reviewed. Loading software may or may not be a sufficient manifestation of assent. Any action taken by staff, regardless of their authority to bind the organization to an acquisition in an online environment, may authorize the license. Must the terms appear on the home page of a site or is it legally adequate to post a button on the page that would take the user to a screen with terms and conditions for use? Must a user click "I agree" in order to manifest assent? Most authorities recommend that the user be required to agree to the terms and conditions by taking some type of formal step such as clicking "I agree" before being bound by them. Again, staff who are unaware of the legal consequences may undertake the initial step of adding material to the collection by using the site, by bypassing the click button, or even by clicking "I agree."

The library has a right to return the software in the same manner that a library could return a book that upon inspection was found inappropriate for the collection.

Finally, the Virginia statute does not alter the general burden of proof in an infringement, contract, or other action. The Virginia library amendment does nothing to clarify the relationship between a contract that violates a public policy, including whether such policy is under the federal copyright law, and one that does not.^[41]

Consumer Protection and Warranties

A UCITA license will affect more than copyright law. It will fundamentally change the way consumers interact with software and information vendors. Because libraries are among the largest consumers of software and digital information, the language in licenses is critical to users. Several provisions of UCITA illustrate how this legislation reshapes the relationship between information consumers and information vendors. Some of these sections create doubts about whether software transactions are covered by consumer protection laws.

Despite the lack of opportunity to review the terms of a license, a licensee may be bound by "manifesting assent" to the terms. Section 112 defines how a person or an electronic agent manifests assent and includes formation of a contract by double-clicking after payment and delivery.^[42] This section coupled with Section 208, which provides that the terms of a record become the terms of the contract if the party manifests assent^[43] to the terms, permits vendors to impose potentially restrictive terms on use of information postpurchase or to impose additional costs by requiring return of goods rather than preacquisition presentation of terms. There are no presale reviews of the product.

Under a shrink-wrap or click-through license subject to this legislation, vendors could unilaterally modify the terms of a contract during its operation.^[44] Such a modification could be viewed as accepted by the licensee by their continued use of the software or information. Courts likely will enforce the modified contract unless it is "manifestly unreasonable." This is one of the most pernicious part of the model legislation and opponents view it as the worst kind of bait and switch to lure consumers to the product. In the context of mass-market sales of software in a box in a store, it is not feasible to disclose the entire license prior to the sale of the software; however, it makes no sense to permit postassent contractual modifications to a click-through license.

In spite of the 2002 amendments, which provide that state consumer protection laws apply when a license is otherwise silent on the matter, UCITA permits copyright holders to include clauses in their licenses that disclaim warranties and liabilities. The model legislation immunizes software and information providers from liability when the software they provide is "flawed" or "buggy." Vendors are afforded similar protection when the documentation is inadequate or incorrect. The provision allows a vendor to sell "as is" even when the vendor knows of the defects and fails to disclose the problem to the user.^[45] A licensee will have the benefit of an implied license only when it undertakes a reasonable inspection that fails to reveal the defect. Moreover, the Virginia version of UCITA states that the occasional failure to provide service does not constitute a breach of contract.^[46] This leaves libraries and other subscribers to online databases without a remedy when online services are inaccessible to their patrons.

A self-help provision^[47] that allowed software or content providers to remotely disable software if they had reason to believe that a licensee was in violation of its license agreement was particularly controversial. Late payments or perceived misuse of a product were deemed just cause to trigger the self-help provisions. A vendor could disable the software even for an unknowing and minor infraction of the license. The model legislation was redrafted to require reasonable notice before this remedy could be effected.^[48] Although the 2002 Amendments banned "electronic self-help," the problem still exists

because the statute permits “electronic regulation of performance,” which is essentially the same thing. These measures could further complicate the mission of libraries because electronic products may disappear at the expiration of the term of the license. The disappearance of information without notice could hamper preservation activities.

Finally, UCITA legitimizes e-mail, recognizing communications by this method for the purposes of contracting and legal notice.^[49] While this is a laudable goal, the statute falls short by failing to require that the addressee actually read the message. Electronic mail notification is recognized if the message is properly addressed and received. Messages thwarted by full in-boxes or buggy e-mail are just as effective as messages properly delivered.

First Amendment Issues

Even traditional First Amendment principles such as fair comment are called into question by the UCITA statute. Access to software or information may be conditioned on a licensed agreement that says the software package or information cannot be reviewed or critiqued by a magazine or newspaper without the permission of the vendor. This would allow a vendor to preclude public comment or criticism of the product by preventing negative reviews from appearing in print to the detriment of users and potential purchasers of the information or software; however, in July 2002, NCCUSL amended this section so that vendors will no longer be able to silence critics through contract.^[50] Provisions that prohibit users, in most cases, from reverse engineering a product are permitted by UCITA. Users may be allowed to reverse engineer for interoperability.

Choice of Forum/Choice of Law

Under a UCITA contract the licensor may designate the forum, generally the state in which the software producer is located, in which any issues would be litigated, making it inconvenient if not impossible for the licensee to resolve the issue. In other cases, the licensor may not designate the state where the issues will be litigated, but may designate instead the body of law that the court must consider.^[51] It is likely that such licenses will designate a body of state law that includes UCITA with its clauses favorable to the producers. Venue and choice of law clauses may render some state contracts unenforceable. For the resolution of conflicts between state institutions such as colleges and universities or public libraries and licensors, jurisdiction must be within the state. Typically a state agent authorized to bind the state cannot enter into a contract that specifies the law of another state as controlling. For others, these sections continue to present significant issues.

Some states that considered the enactment of UCITA found these provisions particularly objectionable and passed “bomb-shelter” legislation to protect the residents

of their state. For example, North Carolina legislators passed language that provides.

§ 66-329 Choice of Law in Computer Information Agreement.

A choice of law provision in a computer information agreement which provides that the contract is to be interpreted pursuant to the laws of a state that has enacted the UCITA, as proposed by the NCCUSL, or any substantially similar law, is voidable and the agreement shall be interpreted pursuant to the laws of this state if the party against whom enforcement of the choice of law provisions is sought is a resident of this state or has its principal place of business located in this state. For purposes of this section, a “computer information agreement” means an agreement that would be governed by the UCITA or substantially similar law as enacted in the state specified in the choice of law provisions if that state’s law were applied to the agreement. This section may not be varied by agreement of the parties. This section shall remain in force until such time as the North Carolina General Assembly enacts the UCITA or any substantially similar law and that law becomes effective.^[52]

This poison-pill type of legislation has been passed or considered by states that do not have to appease technology industries.^[53] It protects the interests of the citizens of the state while giving UCITA time to prove that it is working in Virginia and Maryland.

Although support for UCITA has declined, narrower efforts at reform have simultaneously been underway. One such effort resulted in recent amendments to UCC Article 1 regarding, among other things, choice of law.^[54] Previously, contracts containing choice of law provisions had to bear a “reasonable relation” to the designated state whose law would govern.^[55] The revision, however, gives greater autonomy to the parties by providing that choice of law clauses can be upheld “whether or not the transaction bears a relation to the State designated. . . .”^[56] Because courts currently rely on the UCC for transactions in computer information, if adopted by the states, this change could have a similar impact as that proposed by UCITA. Of the 28 states that have adopted the Article 1 amendments, however, all have rejected this particular change and have chosen to use alternate wording which maintains some form of the “reasonable relation” requirement.

Unreasonable Standard Amendment

The standard for unconscionability proposed by the drafters of UCITA in Section 111 requires that a term must “shock the conscience” to be void on any ground other than public policy under section 105. This is a very high legal standard. AFFECT proposed a change from an unconscionable standard to an unconscionable or unexpected standard for determining whether a term within a standard form contract is valid.

Section 111. Unconscionable or Unexpected Contract or Term

- (a) If a court as a matter of law finds a contract or a term thereof to have been unconscionable or to have frustrated the reasonable expectations of the nondrafting party at the time it was made, the court may refuse to enforce the contract, enforce the remainder of the contract without the unconscionable or unexpected term, or limit the application of the unconscionable or unexpected term so as to avoid an unconscionable or unexpected result.
- (b) If it is claimed or appears to the court that a contract or term thereof may be unconscionable or unexpected, the parties must be afforded a reasonable opportunity to present evidence as to its commercial setting, purpose, and effect to aid the court in making the determination.^[57]

A standard form contract under UCITA, however, may include a surprising term that does not reach the level of a public policy concern. The statute as drafted does not address this situation. The reasonable expectations standard is more appropriate than the unconscionability standard in a standard form contract under UCITA because it facilitates evaluation of the term from the perspective of the nondrafting party. The term does not necessarily need to “shock the conscience.” The library community believes that many, if not all, unconscionable terms, by definition, would frustrate the reasonable expectations of the nondrafting party.^[58]

COURTS AND RELATED LEGISLATION

Fear of the unknown causes publishers to include restrictive language. The last thing either side wants is litigation. UCITA offers a new legal framework by which libraries and educational institutions would acquire and use information, and which would affect the ability of these organizations to carry out their missions. However, because of the many controversial and unresolved issues surrounding UCITA, it has been enacted in only two states.

In the absence of a legal template such as UCITA, courts have relied on existing copyright and intellectual property law, industry norms, and the UCC in dealing with computer information transactions. Although the United States Supreme Court has yet to provide any definitive ruling, several lower courts have heard cases arising from shrink-wrap or click-wrap license agreements. These cases present two central issues. First, whether shrink-wrap and click-wrap licenses are enforceable generally or, alternatively, should be treated as unenforceable contracts of adhesion. Second, if licenses are found to be enforceable, whether particular terms of the license which override traditional copyright exemptions, such as the

doctrines of fair use and first sale, are enforceable. Courts remain divided on the first issue of general enforceability. Some decisions, such as *Meridian Project Systems, Inc. v. Hardin Construction Company, LLC*, 426 F. Supp. 2d 1101 (E.D. Cal. 2006), uphold licenses.^[59] Others, such as *Wachter Management Company v. Dexter & Chaney, Inc.*, 144 P.3d 747 (Kan. 2006), find such licenses to be unenforceable under the UCC.^[60]

Two early decisions from the U.S. Court of Appeals for the Fifth and Seventh Circuits take opposing positions with regard to the second issue. In *Vault Corporation v. Quaid Software Ltd.*, 847 F.2d 255 (5th Cir. 1988), the court determined that shrink-wrap license terms which prohibited the copying of a computer software program were preempted by a Copyright Act limitation on the exclusive rights of the program’s creator.^[61] In *ProDC, Inc. v. Zeidenberg*, 86 F.3d 1447 (7th Cir. 1996), however, the court concluded that the agreed-to terms of a shrink-wrap license under state law are not preempted by federal copyright law.^[62] In recent years, in cases where the license is held to be enforceable generally, courts are usually in agreement with *ProCD* regarding preemption. The overall trend appears to be toward enforcement of shrink-wrap license agreements when, whether made available before or after purchase, the licensee has an opportunity to review the terms and accept or reject them. Thus, in spite of NCCUSL’s failure to gain wide acceptance of UCITA, decisions by the courts could ultimately have a similar impact on the way information transactions are viewed.

A recent amendment to the UCC adds to the difficulty courts face. Traditionally, courts have applied UCC standards to transactions that involve a mix of goods and information and, in some instances, those that deal solely with information. This is because the UCC is well established and, for the most part, consistent across all states. In 2004, however, NCCUSL and ALI amended UCC Article 2 to explicitly exclude information from the definition of “goods” covered by the UCC.^[63] Such a change could be problematic because it directs courts to discontinue application of the UCC in pure information transactions, and creates doubt about its applicability in mixed transactions, without providing a framework to replace it. Because most states have not yet adopted this change, its full impact remains to be seen. Currently, most courts continue to interpret the UCC with enough flexibility to govern software and other information-related transactions.^[64]

CONCLUSION

The trend is no longer the acquisition of physical copies of information but rather the access to information in a digital format. Libraries are seeing increased use of click-through licenses and shrink-wrap licenses as they acquire

digital supplements to traditional products, receive updates to online products, and gain access to new sources. Limiting rights which are otherwise available to libraries and users under the Copyright Act is generally not an issue when such limitations are the result of negotiation between the parties. The problem with UCITA, however, is that it allows for these rights to be limited without notice or agreement by the consumer.

Whatever the direction this area of the law takes, it is clear that librarians and information specialists must learn as much as possible about the issues and be watchful of restrictions applicable to their users and institutions. Users should expect nothing less in a license agreement than rights librarians are urged to ensure in a negotiated agreement.^[65] Understanding and complying with licenses will be a cost of doing business. Look to your licenses, print copies of them, and date them. Educate staff and users about terms of use recognizing the copyrights of the licensor and your rights as licensee. Like risk management decisions in determining whether a particular use of a copy is a fair use, reviewing licenses and determining the extent to which you can use the information is a cost of business.

Unions in Public and Academic Libraries

Kathleen de la Peña McCook

School of Library and Information Science, University of South Florida, Tampa, Florida, U.S.A.

Abstract

The role of unions and collective bargaining in U.S. public and academic libraries is stated with a summary of historical development. After noting the lack of national association attention to unionization, the evolution of the American Library Association-Allied Professional Association (ALA-APA) is described. The connection between human rights and unions is discussed. Appendices with URLs of public and academic library worker unions in the United States and Canada as compiled by the author are included.

INTRODUCTION

Unions contribute to a stable, productive workforce—where workers have a say in improving their jobs. Library workers in public, academic, and school libraries have organized in unions for better wages, working conditions, and benefits. In 2006 taken as a whole, U.S. union library workers earned almost 21% more than their nonunion counterparts.^[1,2] A stratified sample of 3418 public and academic libraries found the union advantage extends across all library sizes and types. Union membership varied by region from a high of 15.9% in the North Atlantic to a low of 1.9% in the Southeast. This clearly demonstrates the power of unions to raise salaries in the predominantly female, underpaid library world. If wages and salaries are so much higher among unionized library workers, why is union membership—overall, less than 20% of the workforce? There is no simple answer. The field is not monolithic. Academic librarians function in educational settings tied to the fortunes of their colleges or universities and usually—when collective bargaining is in place—to a faculty union. Public librarians work in the public sector in a variety of governmental structures—city, county, district. The professional associations have not placed the betterment of library workers at the center of their agendas as have the American Federation of Teachers (AFT) or the National Education Association (NEA), but have focused on the development of the institution. The largest association in the United States is the American Library Association (ALA), not the American Librarian Association. Nevertheless, many librarians have organized in unions or as part of larger unions. While these may not account for the majority of librarians, they do account for a large number and collective bargaining is an important aspect of the structure of the field's human resource component.

PUBLIC LIBRARIES

The first public library unions were affiliated with the American Federation of Labor (AFL): New York Public Library and the Library of Congress formed in 1917; Boston Public Library and the District of Columbia Public Library formed in 1918 and the Philadelphia Free Library formed in 1919.^[3] Bernard Berelson has examined the historical context of these first public library unions and their dissolution. All but the Library of Congress union disbanded by 1929 due to the overwhelming strength of the opposition or poor leadership.^[4] Of special note is the debate that took place about the status of women as articulated by union organizer/suffragist Maud Malone of the New York Public Library Employees Union.^[5]

In his overview of unionism written for *Library Trends*, “Employee Organization and Collective Bargaining in Libraries,” (1976) Herbert Biblo characterized the years 1934–1949 as the second wave of public library unionism.^[6,7] The passage of the National Labor Relations Act, (also known as the Wagner Act) in 1935 and the creation of the National Labor Relations Board to regulate collective bargaining fostered organizing. The Cleveland Public Library Employees Union was organized as part of the American Federation of State, County, and Municipal Employees (AFSCME, AFL) in 1937, but became part of the State, County, and Municipal Workers of American (SCMWA, CIO) later that year.

Joyce M. Latham has tracked the State County and Municipal Workers of America, a white-collar CIO union, and in particular the development of the Chicago Public Library's Local 88 (1937)—one of “several unions which emerged as a response to the failure of middle class structures in the face of the economic challenges of the Depression.” Latham's work is especially recommended as a thorough and extensive analysis of the origins of public librarians' engagement in challenges to dominant social

and cultural constructs during the period of the late 1930s–1940s.^[8] Other public library unions founded during this period include Milwaukee, Grand Rapids, Detroit, Minneapolis, Atlanta, Newark, Boston, and Wayne County. Biblo notes that these unions came and went with Atlanta and Grand Rapids never reemerging after their initial organization.

During the 1950s no new public library unions emerged, but in the 1960s a new wave of unionization began with locals formed in Philadelphia, Milwaukee, Boston, Chicago, Cleveland, Detroit, Brooklyn, Buffalo and Erie, Washington, DC, Enoch Pratt, Contra Costa, Los Angeles, New York, Queens, Santa Monica, Youngstown, Oshkosh, Berkeley, Bloomfield, Enfield, Morris County, Newark, Oakland, and San Francisco. Additionally, John F. Kennedy's Executive Order of January 17, 1962 on Employee-management cooperation in the Federal service set the tone for increased labor organizing in governments. At the state level some enacted laws like California's Meyers-Milius-Brown Act passed in 1968 to govern labor relations in local governments. Librarian unionism was documented by Melvin S. Goldstein in his 1968 report on collective bargaining efforts on behalf of professional librarians in the United States which included digests of collective bargaining agreements currently then in force as well as the status of negotiations.^[9]

At the 1975 watershed conference, "Collective Bargaining in Libraries," Don Wasserman of AFSCME, presented the context for increased bargaining activity in the public sector and noted that bargaining entered more readily into "mission of the agency," than had blue-collar workers.^[10] In his 1975 monograph, *Unionization: The Viewpoint of Librarians*, Theodore Guyton accounted for the emergence of library labor unions, their goals, and their patterns of growth. His study provides a solid overview of unionization grounded in labor history and theory and includes a survey of librarians' attitudes toward unionization.^[3]

The high-water mark of library union literature came in 1981 with the publication of *Librarians and Labor Relations* which assessed economics, politics, and history in light of new laws, court decisions, and changing personnel trends. The volume examined librarian-management relations and placed library worker unionizing in the larger context of the labor movement.^[11] Doreen Lilore, a former president of a public library local and staff member at AFSCME, wrote an exceptional study of the state of public library unions in 1984 with attention to negotiating the labor agreement, contract administration, analysis of grievance procedures, and a content analysis of public library labor agreements. Her review of the external interaction between the local and management is a major contribution to the history of public library unionism^[12] and built on the earlier analysis by Joseph Vignone.^[13]

However, after the 1980s the literature and reporting of public library unionism declined. Public sector unions

came under much duress after the Professional Air Traffic Controllers Organization (PATCO) strike in 1981 and the Reagan testing of the strength of the labor movement.^[14] The ALA focused on issues of pay equity and comparable worth during the 1980s and 1990s, but did not provide a forum for ongoing discussion of labor issues or unions within the association.

Public library workers' unionization issues are very situational and differ greatly from library to library. Much depends on the larger context of unionization in a government jurisdiction. If there is an overall organizing unit of government employees—AFSCME or Service Employees International Union (SEIU)—then library workers might be a part of the larger union. In other cases librarians organize as locals of larger units. While one library might divide workers between librarians and clerical and support workers, another might combine them into one local. Weber's 1992 article on support staff unions in Ohio demonstrates the need for unions to reflect local and state situations. For example, at the time of his article the Toledo-Lucas County Public Library had two unions. Office, clerical, and maintenance employees were represented by the Communication Workers of America and the librarian local under the Marine Engineers Beneficial Association.^[15]

In 2002 the journal, *Public Libraries*, published a forum on unions, edited by Hampton (Skip) Auld. The discussion was spurred by the support of some ALA members for striking Marriott hotel workers during the Association's 2001 conference.^[16] Ann Sparanese, a public library shop steward and her local's delegate to the County Labor Council, expressed her opinion: "I do think the union helps ensure fairness and respect on the job and is a powerful shield for all employees against a management that would like to act against an employee without doing the necessary homework."^[17]

The longest strike in the history of public librarianship—89 days—by the 800 members of CUPE (Canadian Union of Public Employees) 391 of the Vancouver Public Library in summer 2007 was documented in an extensive essay by Anita Galanopoulos. The CUPE 391 strike was for pay equity, improved benefits, rights for part-time and auxiliary workers and better job security/technological change protection. The "Bargaining and Strike Chronology" included on her essay provides a detailed look at the blueprint of a strike.^[18]

See Appendix I. for a list of public library unions in the United States and Canada.

ACADEMIC UNIONS

Academic library workers, unlike public library workers, almost never organize as a local within a larger union. Herbert Biblo noted that the Librarian Shop, Howard University, Local 10 UFWA, CIO seems to have been the first

collective bargaining agreement to cover an academic library staff in the United States (1945).^[6] However, since the beginning of formal collective bargaining involving college faculty academic librarians have participated in faculty bargaining units based on a community of interest.

The three unions that account for the majority of unionized academic librarians are the American Association of University Professors (AAUP), the AFT, and the NEA. Those wishing a foundational study of the growth of the AFT and the NEA should refer to *Blackboard Unions*.^[19]

The literature of academic library unionism is scant. Weatherford's 1976 Council on Library Resources study, *Collective Bargaining and the Academic Librarian*, places library bargaining in the context of the national organizations as he summarized the commingled history of academic librarians and classroom faculty. He also underscored the role of faculty status for librarians vis-à-vis the librarians' participation in the bargaining unit.^[20,21] In the literature of academic librarianship continued concern over faculty status has seemed to override discussion of collective bargaining issues.^[22,23]

At the national level the Association of College and Research Libraries (ACRL) intertwines issues of faculty status and collective bargaining. The policy regarding collective bargaining current as of 2008 is that "academic librarians shall be included on the same basis as their faculty colleagues in units for collective bargaining. Such units shall be guided by the standards and guidelines of ACRL pertaining to faculty and academic status."^[24,25]

The most comprehensive source for unionization information about higher education is *The Directory of Faculty Contracts and Bargaining Agents in Institutions of Higher Education* a compilation of every collective bargaining relationship covering faculty in the United States. As of January 2006, over 375,000 faculties had union representation in the United States organized into 575 separate bargaining units and distributed across 491 institutions or systems of higher education with 1125 campuses.^[26]

A state of the art of support staff unionization in 1986 and a literature review: *Unions for Academic Library Support Staff* examined unionization at 176 academic libraries.^[27] There is no single list of support staff unions in academic libraries. Collective bargaining generally encompasses multiple job classifications on a campus such as AFSCME or SEIU.

The literature of academic librarianship has few discussions of faculty unionism. However, one recent essay, "Librarians as Key Players in Faculty Unions," that describes the role of library faculty at Eastern Washington University provides insight into the articulation of faculty status for librarians and collective bargaining. The essay demonstrates the collegiality developed through teaching and library faculty working toward common goals.^[28] More articles that provide a functional analysis of the role of unionism in faculty worklife would contribute to better

understanding of the importance of unions to academic librarians.

A rare program at a national conference sponsored by the American Library Association-Allied Professional Association (ALA-APA) at the ALA Conference in New Orleans on June 25, 2006 addressed the role of unions in academic libraries. John Buschman, one of the presenters, summarized: "unionized library faculty have both rights and responsibilities to the library and its services as a whole, and their sponsoring institution. If the status is meaningful beyond a mere title, then librarians must take the responsibilities and the power they have seriously and utilize them judiciously, and this means going well beyond pleasing the boss."^[29]

See Appendix II. For a list of academic library unions in the United States and Canada.

Unions and the ALA

The lack of ALA's focus on unions has been noted by many researchers. After a short-lived Library Union Round Table that existed from 1938 until the 1950s there was no formal entity in the national association that addressed union concern. The ALA's Office for Library Personnel Resources did develop and distribute a packet on Unionization and Collective Bargaining in 1982 as part of that Office's overall commitment to library personnel issues under the stewardship of Margaret Myers.^[30] A search of the ALA's archives turns up very little information about library unions and collective bargaining.

The election of Maurice J. Freedman as president of the ALA in 2001 saw a new focus on library worklife. Freedman established a Special Presidential Task Force on Better Salaries and Pay Equity. As part of this initiative the Task Force published the "Advocating for Better Salaries and Pay Equity Toolkit" coordinated by Margaret Myers, retired director of ALA's Office for Library Personnel Resources that included contact information for and links to unions, FAQs on unions in libraries, and a sample neutrality agreement.^[31] This work led to the formation of the Library Advisory Committee to the AFSCME and a Library Workers Caucus. The union working group also connected with SEIU, which reported on the relative pay and benefits of union and nonunion library workers.^[32]

With the ALA climate for considering library worklife issues changing in the twenty-first century the ALA-APA was established in June 2001 as a companion organization to the ALA. The ALA-APA is a nonprofit organization for the purpose of promoting "the mutual professional interests of librarians and other library workers." It enables certification of individuals in specializations beyond the initial professional degree and also has the charge of advocacy for the "mutual professional interests of librarians and other library workers."

The union subcommittee of ALA-APA is charged: 1) to investigate the extent of the presence and role of unions

among library workers; 2) to report findings to the ALA-APA Standing Committee on the Salaries and Status of Library Workers; 3) to work towards the initiation of a relationship and dialogue among ALA, ALA-APA, and national unions representing library workers, in order to improve their salaries, working conditions and status; 4) to encourage ongoing research and publishing on unionization in libraries; 5) to develop union support and advocacy materials for the Better Salaries Task Force Tool Kit; and 6) to be the permanent interest group within ALA-APA that would serve as a resource for both active and developing unions of library workers.^[33]

Unions Today

There is no single source that lists all unions in which library workers participate. The author has created a list of public and academic unions with links to Web sites as appendices to this entry. These lists were put together by numerous searches state by state and may not be comprehensive, but they are the single most complete source of union information at this writing. They will be updated at the *Union Librarian* blog.^[34] Readers should be aware that there is some fluidity to unions across the United States and Canada and some data may have changed since this entry was submitted. Library workers belong to a variety of unions including, but not limited to the AAUP, the AFT, AFSCME, National Association of Government Employees, SEIU, United Autoworkers, United Service and Allied Workers of RI, United Public Employees of California (UPEC), United Service and Allied Workers of RI.

Unions and Human Rights

In 2008 the world celebrated the 60th anniversary of the Universal Declaration of Human Rights (UDHR). During the drafting of the Declaration there had been tension between the World Federation of Trade and the International Labor Organization about the inclusion of union rights. Mrs. Roosevelt “explained that the United States delegation considered that the right to form and join trade unions was an essential element of freedom.”^[35] Unionization as a human right was included in the UDHR as Article 23.

Article 23.

1. Everyone has the right to work, to free choice of employment, to just and favorable conditions of work and to protection against unemployment.
2. Everyone, without any discrimination, has the right to equal pay for equal work.
3. Everyone who works has the right to just and favorable remuneration ensuring for himself and his family an existence worthy of human dignity, and supplemented, if necessary, by other means of social protection.

4. Everyone has the right to form and to join trade unions for the protection of his interests.^[36]

Sixty years later, unions continue to be viewed as fundamental to democracy. Elaine Bernard wrote in 2008: “Unions are the premier institution of a free, democratic society, promoting democracy in the workplace, as well as economic and social justice, and equality. They have this role because they are instruments of transformation of members and of society at large. In this wonderful transformation rests the real power of unions.”^[37]

The democratic victories in the 2008 general U.S. elections had enthusiastic support from unions. Unions to which the majority of library workers belong (AFSCME, AFT, NEA, SEIU) contributed funds and volunteers to get out the vote. It remains to be seen as the Democratic Party holds power in the federal government if the more positive climate for unionization provides an opportunity for unions to grow among library workers in the public and educational sectors.^[38]

New York Institute of Technology, <http://www.aaupatnyit.org/>

United University Professions, <http://www.uupinfo.org/>

United University Professions (UUP) is the union representing more than 31,000 academic and professional faculties on 29 State University of New York campuses, plus System Administration, Empire State College, and the New York State Theatre Institute. UUP is affiliated with the New York State United Teachers and the American Federation of Teachers, AFL-CIO.

With some 800 job titles included in the bargaining unit, UUP reflects the diversity of the State University. Members include Librarians.

United Kingdom: Archives and Archival Science

Helen Forde

Department of Information Studies, University College London, London, U.K.

Abstract

This entry traces the development of record keeping and archives services in the United Kingdom, highlighting the differences between the constituent home countries, local authority responsibilities, and the diversity of business, religious and community archives. It looks at the development of the archive profession and training, and suggests that information management may become the way the profession develops in an electronic age. The role of the main professional organizations and societies relating to archives and records management is outlined, with an emphasis on the crucial advocacy role they play in ensuring that the importance of the records, in whatever format, is not overlooked.

INTRODUCTION

Archives and records in the United Kingdom are an unrivaled source of historical information with some of the main series of national archives surviving in an unbroken tradition from the twelfth century. As the United Kingdom embraces four different home countries, the arrangements for the records and archives vary in each. This is further complicated by the different legislative systems in Scotland and by the devolution of Scotland and Wales in the recent past. Other archives of businesses, religions, local authorities, and communities also differ in their arrangements for records management and permanent preservation with globalization resulting in additional complexities.

LEGISLATION AND ACCOMMODATION FOR ARCHIVES AND RECORDS

England and Wales

The Public Record Office (PRO) Act 1838 was the first legislation for archival material in England and Wales, bringing together the records of the ancient departments of state, in particular, the Exchequer, Chancery and Courts of Law in a government department, the PRO headed by the Master of the Rolls. It did not cover papers held in government departments, though these were often transferred once the PRO, as a repository in Chancery Lane in central London, became a place of safekeeping. An Order in Council of 1852 regularized the existing situation by extending the remit of the Master of the Rolls, but the PRO staff had no control over selection in departments nor was there any provision for the destruction of unwanted material. Access issues were not addressed, although search rooms were provided in the late

nineteenth century additions to the PRO building in Chancery Lane.

In 1869, the Royal Commission on Historical Manuscripts was created to locate and provide access to records held in private collections. It published reports on them, providing details on the type of information contained in the manuscripts and where they were located. It continued this work on the premises of, and in conjunction with the staff at the PRO but in 1959 it received a further royal warrant and moved to new accommodation in Quality Court, Chancery Lane. By this time, it was in charge of the National Register of Archives (created in 1945), a project that was deliberately focused on nongovernmental archives and which was the forerunner of the more ambitious and all-embracing electronic databases that are now current.

Sir Hilary Jenkinson (1882–1961) was one of the dominant figures in the early twentieth century as a shaper of British archival theory. This was to become the basis of practice both at home and in many of the then colonies. He worked at the PRO, eventually becoming Deputy Keeper (effective head) in 1947, and it was here that he developed the concepts which were outlined in his book *A Manual of Archive Administration* (Oxford: Clarendon Press, 1922). He used his experiences to direct and guide the emerging profession to ensure that modern records, as well as those of greater age, were catered for adequately and many of his innovations, such as The National Register of Archives, survived well after his death.

After the Second World War, concern over the uncoordinated accumulation of records led to the publication of a report by the Grigg Committee (Command Paper 9163) in 1954 recommending

- Clear reviewing procedures for selection by the department.
- The appointment of departmental record officers.

- An advisory role for the PRO and the appointment of a records administration officer and staff to oversee the new procedures.
- The transfer of responsibility for the PRO from the Master of the Rolls to a minister.
- Access provision to material held by the PRO for material over 50 years old unless there were special considerations.
- The inclusion of cinematograph film, photographs, and sound recordings as public records where appropriate.

These provisions were incorporated into the Public Records Act 1958, which was followed by a further Act in 1968 to reduce the closure period to 30 years. Concern that records of the Second World War should be released en bloc, apart from those of service personnel, led to their release in 1972, following the precedent of the release of those of the First World War.

By 1976, pressure on the space required to store the increasing volume of national archives resulted in the opening of a new facility at Kew, in south west London, to which the nineteenth and twentieth century holdings were transferred. The latter was extended in 1996 to house the entire archive and the central London repository was closed apart from a Family Record Centre for genealogists, run jointly with the Office of National Statistics. This closed in 2008 due, in part, to the increasing number of archival resources available online.

Access provisions were changed by the Freedom of Information Act, which came into force in 2005 guaranteeing a general right of access to information held by public authorities subject to certain provisions about public interest. A Code of Practice was issued from the Lord Chancellor's Office to guide departments in carrying out the Act. Further consultation is currently (2008) being conducted into the feasibility of a reduction of the 30 year rule. An Access to environmental information is regulated by the EU Directive 2003/2004 EC, replacing the 1992 Environmental Information Regulations. This ensures the right of access to environmental information held by public bodies.

Data Protection legislation, initially (1984) referring only to data held on individuals electronically, was revised by the Data Protection Act passed in 1998 to cover the protection of data on individuals in all formats, while permitting the legitimate collection of such data by organizations that require access for research purposes.

The partnership established in 2003 between the Royal Commission on Historical Manuscripts (HMC) and the then PRO vested the responsibilities of the Commissioners in the Keeper of Public Records, who was thereafter known as the Chief Executive of The National Archives (TNA). This enabled TNA to advise about the location and the condition of private papers and manuscripts, in addition to managing public records. The TNA now comprises

the former PRO, the Royal Commission on Historical Manuscripts, the Office of Public Sector Information, and Her Majesty's Stationery Office.

Despite the remit of the PRO as the government archive, some private collections have been deposited with the public records since, at the time of transfer, the record office was regarded as the most appropriate location. These include some Church of England material, notably the probate records for the Archdiocese of Canterbury. These records are among the most regularly consulted since they cover the testamentary records of many famous, and not so famous, people up to 1858. Together with other records of interest to genealogists these are now online.

Records designated as public records on account of their enduring value are mainly kept at TNA but a significant minority are kept in over 200 other repositories, many of them are local record offices. These are known as Places of Deposit, and the public archives held in each are subject to the same regulation as those held centrally. The National Advisory Service (the merger of the Royal Commission on Historical Manuscripts and the Archive Inspection Unit of the former PRO) has published *The National Archives Standard for Record Repositories* setting out best practice for archive provision. It is supported by a Framework of Standards, covering a wider range of best practice to cater for the equally wide range of repositories. The governing bodies of those holding public records are asked to subscribe to the Standard, and those attaining the essential requirements are approved by TNA.

Scotland

Responsibility for the archives in Scotland is vested in the Keeper of Records and legislation consequently relates to this post. The Public Records (Scotland) Act 1937 was largely concerned with the transfer to the Keeper of the records of the central and local courts of law as well as government departments, agencies, nondepartmental public bodies, statutory bodies corporate, and local authorities. In 1937, the Keeper also had the responsibility for the creation and maintenance of the Register of Saisines (Seisins [The instrument [in Scotland] by which the possession of feudal property is proved. (*Oxford English Dictionary*)]), but that function was split by the Public Registers and Records (Scotland) Act 1948 as a recognition of the difference between the two activities. The U.K. wide Public Records Act 1958 (see above) enabled the transfer of records of public bodies operating partly or wholly in Scotland to the National Archives of Scotland (NAS), and provisions similar to those outlined in the 1958 Act for selection, transfer, and preservation of the records were adopted by the Scottish Office in 1962 for public bodies in Scotland; at the same time similar access provisions were adopted together with the reduction to a 30 year limit in 1967.

The Keeper has also been able to take in private records, following an amendment to the Act in 1985, in which procedures for disposal were set out and the Scottish Advisory Council was established. Data Protection provisions for Scotland are in line with those for England and Wales; similarly, the Freedom of Information Act (Scotland) 2002 covers public bodies in Scotland. Currently (2008), a review of legislation on government records in Scotland is being carried out to ensure that they are appropriate and accessible; this follows the recommendation of the Shaw report (2007) (<http://www.scotland.gov.uk/Publications/2007/11/20104729/>). The NAS is situated on three sites in Edinburgh, two of which are open to the public, General Register House and West Register House. In addition, Thomas Thomson House, in the west of Edinburgh is its main repository and also houses the conservation department and offices.

Northern Ireland

The Public Records Act (Northern Ireland) 1923 established the Public Record Office of Northern Ireland (PRONI) shortly after the destruction of many of the Irish public records in the fire in the Four Courts, Dublin in 1922. The Act stipulated that it was legal for PRONI to bring in records, which were not expressly created by government as a deliberate attempt to ensure that as many documents as possible were retained to compensate for the very serious loss in Dublin. Private records, in particular, were targeted for collection, safekeeping, and public access. After the Second World War, the pressure on storage space increased and the Northern Ireland government followed the recommendations of the 1954 Grigg report (see above) to introduce regular reviews of material in government departments and disposal schedules. In 1976, in accordance with the practice elsewhere in the United Kingdom, the 30 year rule was introduced.

The Public Record Office of Northern Ireland has moved to different parts of the government of Northern Ireland being part of the Department of Finance from 1924 to 1984; part of the Department of the Environment until it changed to become an executive agency in 1995; and finally part of the Department of Culture, Arts and Leisure (DCAL) in 1999. Following the review of Public Administration in 2006, it ceased to be an agency and its status is now as a division of DCAL. The frequent changes have been due, in part, to the recent troubled history of devolved government in Northern Ireland. In response to demand from government departments, PRONI drew up the Northern Ireland Record Management Standard (NIRMS) in 2002.

Wales

Welsh public records are governed by the same provisions as those in England; they were moved to the PRO in the

mid-nineteenth century but requests for a specific record office for Wales were being made in a bill introduced to Parliament as early as 1913. No further progress was made until the Public Records Act 1958 nominated repositories in Wales as suitable Places of Deposit for public records (see above) and also authorized the return of the bulk of the Welsh records to the National Library of Wales.

The Government of Wales Act 1997 made provision for the concept of Welsh Public Records, which, in the following Government of Wales Act 2006, included a list of bodies whose records were to be accorded that status. The U.K. Public Records Acts 1958 and 1967 remain in force until provisions are established.

Local Records in England and Wales

No specific legislation relates to local administrative records or the provision of county or borough archive services. The Local Government (Records) Act 1962 conferred discretionary powers on local authorities (now including all county councils, London boroughs, metropolitan districts, and unitary councils) to provide a limited archive service relating to the acquisition of and access to archival material, not restricted to official material. Stewardship and wider advisory powers were not included. The Local Government Act 1972 (s224) required local authorities to make proper arrangements for archives belonging to, or in the custody of, officers of the council; this was followed in 1999 by guidance on “proper arrangements,” issued by the department then responsible, the Department of the Environment, Transport, and the Regions. It refers to the management of records, in whatever format and the historical records that should be kept by an established archive.

Manorial records, held in local record offices are nominally under the custodianship of the Master of the Rolls and come under special protection due to the enduring legal position of many of the properties mentioned in the records. All pre-1925 manorial documents, except deeds and other evidence of title, are protected under the regulations published in the 1924 amendment to the Law of Property Act 1922, (s122A). Original responsibility for maintaining the register of manorial property was undertaken by the PRO on behalf of the Master of the Rolls, then by the Royal Commission on Historical Manuscripts following the Public Records Act 1958, and subsequently by TNA; Historical Manuscripts Commission when the two combined in 2003. The rules prevent the removal of manorial documents from England and Wales without the permission of the Master of the Rolls, require ownership details, or changes, to be registered, require custodians to provide safe and appropriate storage conditions and permit the removal of any documents to a more appropriate place of deposit if necessary.

Responsibility for documents relating to tithes paid to the Church of England is also held by the Master of the

Rolls and also exercised by TNA: Historical Manuscripts Commission. The original tithe apportionment maps and schedules, created as a result of the Tithe Apportionment Act 1838 (6&7 Will.IV, c.7) are held at TNA, and the two copies are held locally, often by now in the appropriate county record office. Rules have been issued relating to the care and custody of the records.

The Parochial Records and Registers Measure, passed by the General Synod of the Church of England in 1978, was a recognition of the public interest in these records and the need to ensure their security and preservation as well as providing access. Diocesan record offices had been established by the Parochial Records and Registers Measure 1929 but in practice, the spread of local record offices has resulted in many being designated as diocesan repositories. The principal duties imposed by the measure include the deposit of all noncurrent records and registers over 100 years old in the appointed diocesan office with reasonable access during working hours and regular inspection of the conditions provided for those which are retained.

The Local Government (Wales) Act 1994 required all new unitary authorities to provide plans to the Secretary of State for proposed archive delivery services. These were to include all records belonging to the local authority or of which they had custody.

ARCHIVE SERVICES

The functions of TNA in all three home countries are broadly similar; the main principles remain the provision of selection, preservation, and access services, together with advisory services especially on electronic materials.

In England and Wales, TNA offers services to the records management community and all custodians of records with the responsibility for caring for records, including private owners. The National Advisory Services offer advice and guidance on the creation, management, care, and use of records and archives by

- Setting standards and outlining best practice.
- Advising archive professionals using *The National Archives' Standard for Record Repositories*.
- Advising private owners and organizations on archive issues.
- Developing guidance and policies on electronic records management for government.
- Providing advice and guidance for statutory Places of Deposit to ensure the maintenance of high standards of care and access to public records.
- Promoting good records management and the cultural and historical importance of archives for evidence of good governance; this includes business archives and religious archives.

In England, services to users include the provision of resources on-site at the record office in Kew, in south west London. The service varies between the traditional advice to readers delivered in person by knowledgeable staff, to the recent *Your Archives* wiki, a Web site designed to allow users to contribute their knowledge of archival sources held by TNA and other U.K. archives. Development of the TNA web site has also enabled TNA to put its own catalog online for users to consult prior to a visit and to participate with others in the English strand of the beginnings of a virtual national archives catalog for the United Kingdom, *Access to Archives* (A2A). Gradually this objective is being achieved through the Global Search function on the TNA Web site where it is now (2008) possible to access information on collections held both at TNA and elsewhere.

Research services also include corporate research, TNA having been given Independent Research Organization status in 2005. This is frequently undertaken in partnership with university departments whose staff have specialized knowledge of TNA collections but also in the form of applied research in conservation science, information, records and archives management, digital preservation, and the provision of public sector information. It is intended to support decision making in TNA and by extension to the wider archive and library community.

Access services have changed considerably in the recent past, leading to a much wider audience through electronic means. Investment in developing these services has been high, particularly in the digitization of archival material. Access to the basic information remains free but charges are levied for copies of material, which has been downloaded, ensuring continuing income for further investment. Information on the records available in this format is on the relevant Web sites and catalogs. Partnerships, with private genealogical services in particular, have resulted in the management of such digital resources to be undertaken out of the public sector.

Access hours at Kew have increased as a result of the wider focus on citizens' rights. Regular surveys are made by the Public Services Quality Group (PSQG) to measure the satisfaction of users with services and offer users the chance to suggest improvements. These have resulted in changes to improving access and to developing a dialogue with the users.

Scotland, Wales, and Northern Ireland

Like its counterpart in England, NAS offers advice to government departments on all aspects of records management, to public and private owners of historical material and to the general public on using the records in its care. Similarly, it works in partnership with other organizations to promote Scottish archival interests, and it has been to the fore in developing online services, particularly for genealogists.

In Wales, the National Library manages the Welsh archival material deposited there that includes both public records and private transfers. Services are broadly similar to those offered in England and Scotland. The Welsh Assembly has the responsibility for records management services to Assembly departments.

In Northern Ireland, PRONI has the same responsibilities for the Northern Ireland Civil Service records management and the services to users of the record office as the TNA in the other countries.

Local Archives Services

Local authorities in England and Wales manage their own archive services while those that are designated as Places of Deposit for public records (see above) have to comply with the relevant regulations for their safekeeping and access. Most countries and some metropolitan areas have archive services though some combine them with local history centres (e.g., Surrey) or libraries (e.g., Birmingham). A noticeable trend in the last 20 years has been the reduction in the number of county archivists, the posts being either downgraded or being merged with that of those responsible for History Services or Local Studies.

Changes in local government organization and geographical boundaries have resulted in some amalgamations of historic collections or joint services with several contributing partners. The results of the 2007 self-assessment exercise (Nicholas Kingsley 'Self assessment of local authority archives 2007: the results revealed' *Record Keeping*, Winter 2008, pp. 10–15) (see above) suggests that size matters; larger organizations are better able to provide a wider range of services to a higher quality than small organizations which struggle with limited resources. This suggests that further amalgamation may be the only way in which to maintain high service standards.

Local authority archives keep not only the records of that organization covering a wide range of materials including those relating to the Poor Law, health, and education but also many records donated or deposited by the community. These can include solicitors' and estate agents' papers, transport records, business and industrial records, antiquarian material, voluntary organizations' records including those of charitable bodies, local societies and clubs, literary archives, diocesan material (see below) including parish registers, estate and family archives including manorial records, and many other types of archival material local in nature. Court records from the Quarter and Petty Sessions often survive locally, and many hospitals and national health organizations deposit their material with local authority record offices.

The emphasis on delivery for archives, both local and public in the early twenty-first century is on the contribution that the services can make to government initiatives such as education, health care, and citizenship as well as

the insights into historic information that have been the traditional services offered.

ARCHIVES OF HIGHER EDUCATION ORGANIZATIONS

College and university archives are maintained by their institutions, often in conjunction with manuscript and other collections. They vary from the medieval college foundations of Oxford and Cambridge universities to the modern collections of, for example the University of Warwick where many contemporary political and trade union records are kept. Notable alumni of universities often donate their papers to these institutions in later life; these are kept as appropriate but if the content is more applicable to another organization the authors are often advised on which is the more appropriate repository.

Services to readers vary according to institution but the central point of access to descriptions of archives held in higher education organizations is the online *Archives Hub* (<http://www.archiveshub.ac.uk>); this is progressively adding information at collections level and increasingly to complete catalog descriptions. Another higher education cataloging project is AIM25 (<http://www.aim25.ac.uk/>), an organization which provides electronic access to collection level descriptions of the archives of over 90 higher education institutions and learned societies within the greater London area, the name signifying that they are within the orbit of the London ring road, the M25.

BUSINESS ARCHIVES

Many businesses in the United Kingdom hold their own archives, including those which relate to enterprises in both the United Kingdom and abroad. These range from major international companies such as BP, Diageo or Marks and Spencer, banks including the Bank of England and major mining and excavation companies to smaller local organizations. Local record offices frequently aim to retain material where the original business is no longer trading, though it is often in the way of a rescue operation; recently the records of a paper manufacturer, William Sommerville and Son Ltd., a major nineteenth century employer in Midlothian, Scotland were deposited with the Midlothian Local Studies and Archive Service having been salvaged from a skip and this is not at all unusual.

While business archives are private, and therefore not subject to government regulation apart from the requirements for retaining certain financial records, many participate in wider activities to promote education or encourage genealogists to use their resources. The services they offer may be curtailed due to commercial needs and confidentiality agreements but where necessary these are managed sensitively. Initiatives among the larger

organizations include the digitization of N.M. Rothschild & Sons' records relating to the involvement of the banking firm in nineteenth century Brazil and the development of a museum by another banking firm, HBOS, in Edinburgh with a particular remit to promote financial education among schoolchildren. Local businesses may well be associated with other activities in local study centers, contributing photographic and other material to displays. In some areas, communities have come together to ensure the survival of personal and community archives that record past local employment opportunities and businesses (see below).

Business archives are promoted by the Business Archives Council established in 1934 to encourage the preservation of British business records, and to advise on their administration and management. The Council is acutely aware that the continuing existence and accessibility of business archives is closely linked to the fortunes of their owners, and of the need to strengthen rescue activities and respond to collections at risk. Consequently, it keeps in close touch with record offices and local study centers to advise them of opportunities and to encourage the deposit of materials at risk.

FILM AND AUDIOVISUAL ARCHIVES

The British Film Archive was founded in 1935 as a part of the remit of the British Film Institute "to maintain a national repository of films of permanent value." It is recognized internationally as one of the four founders of the International Federation of Film Archives (FIAF). It collects U.K. film of all kinds as well as material produced overseas, and currently (2008) holds over 7 million stills, 1 million transparencies, and 20,000 posters. The collecting policy is wide, including feature films, professional and amateur films, documentaries, propaganda films, and television programs. It is also the official repository for video recordings of Parliamentary proceedings and government films selected for permanent preservation by TNA. The services include involvement in film festivals, regular release of material to be seen at local cinemas, and the release of film and television programs on DVD. The preservation section is housed in premises funded by the late John Paul Getty and the staff work on the restoration of degraded materials with a view to enabling screening. Highly flammable nitrate film is housed separately.

Twelve public sector film archives are established in different parts of the U.K. forming the U.K. film archive forum. The English regional film archives have a remit to collect moving image material of relevance to their region. This includes audiovisual material made either in or by people from each region. Some operate within a record office, such as the Wessex Film Archive at the Hampshire Record Office, others within universities, such as the

Media Archive for Central England (MACE) at Leicester University or the East Anglia Film Archive at the University of East Anglia. Wales and Scotland have their own film archives held in both cases in their respective national libraries, with the same regional emphasis. No dedicated archive exists for Northern Ireland but some film material is available in the Ulster Folk and Transport Museum. The services offered vary according to funding arrangements but often include local screenings, talks to interested groups, and retrieval of material for individual and commercial use.

Specialist film archives include the extensive collections held by the Imperial War Museum, which is dedicated to film and video related to twentieth century conflict involving British and Commonwealth forces. The British Broadcasting Company (BBC) holds about 4 million items from radio and television as well as collections of sheet music and press cuttings. Material is made available both to the BBC and to individuals, and much use is made of the Web site to promote film and sound recordings of notable events and anniversaries.

The British Sound Archive is maintained by the British Library, and it holds over a million discs, 185,000 tapes, and many other sound and video recordings from all over the world, covering the entire range of recorded sound from music, drama, and literature, to oral history and wildlife sounds. The archives range from cylinders made in the late nineteenth century to the latest CD, DVD, and minidisk recordings. It includes copies of commercial recordings issued in the United Kingdom, together with selected commercial recordings from overseas, radio broadcasts and many privately made recordings. Increasingly these are being made available online.

Film and video material held in higher education organizations is promoted by the British Universities Film and Video Council (BUFVC) through its library and viewing and editing facilities.

RELIGIOUS ARCHIVES

Religious archives, other than those of the Church of England (see above), are normally kept either by the denomination in question, in a special library or in local record offices. Although each faith has different arrangements for deposit and access most have Web sites from which it is possible to ascertain opening hours. Dr. Williams' Library in Gordon Square, London is a rich source for a wide variety of both manuscript and printed sources for the history of nonconformity in the United Kingdom. More information is available from the Religious Archives Group of the Society of Archivists and a recent report on the state of religious archives in the United Kingdom (<http://www.nationalarchives.gov.uk/archives/advice-corporate.html>).

The Roman Catholic Church in England maintains diocesan records, some (e.g., in Birmingham) dating back to the seventeenth century although the Roman Catholic church was not officially recognized in England until 1850. The Scottish Catholic Archives are currently (2008) maintained in Edinburgh; many of the archives date back before 1878 when the Hierarchy was re-established in Scotland.

The central archives of the Religious Society of Friends (Quakers) are held in Friends House Library, London though local records, as for other nonconformist groups, are often found in the relevant record office.

The national Baptist archives are held in the Angus Library at Regent's Park College in Oxford and include the records of some local Baptist churches from the seventeenth century, though these are also found in local record offices.

The central archives of the Congregational Union of England and Wales are held in Dr. Williams' Library (see above).

Jewish archives in England are scattered between different synagogues and university deposits, including those of prominent Jews. In Scotland, the Scottish Jewish Archive in Glasgow has been established to collect a wide range of materials to document the history of the Jewish diaspora in Scotland since the eighteenth century.

COMMUNITY ARCHIVES

Community archives have developed during the past 10 years largely as unofficial records of communities where information about earlier activities, including industry, are in the danger of being forgotten. The definition of the term is still being debated but in essence, it is agreed that a community archive should be a collection that includes primary sources, in whatever format, rather than a series of articles. All groups, of whatever origin, are encouraged to contribute to the growing corpus of information held online by CommunityArchives.org.uk as well as collecting their own materials. Typically, they are based on location but can also include literature and arts archives. The movement is supported by the National Council on Archives Community Advisory Group.

RARE MANUSCRIPT LIBRARIES

Many libraries in the United Kingdom hold rare manuscripts including the National Libraries of Scotland and Wales and the British Library in London. The university libraries have major collections and in many cases, individual colleges, especially at the older universities also hold important materials. Professional bodies frequently own library and archival collections donated by former members.

ARCHIVAL PROFESSION

The archival profession in the United Kingdom grew up in the middle of the twentieth century, successor to a long line of record keepers, librarians, and antiquarians who were charged with the care of archival and historical materials. The development of a separate profession after the Second World War was due, at least in part, to the increasing number of archives deposited in local authority care.

Postgraduate courses were originally established at the School of Library, Archive, and Information Studies at University College London (SLAIS), at Liverpool University, and at the University of Wales at Bangor and Aberystwyth. In-house training was provided by some of the larger institutions such as the then PRO (now TNA) and the Bodleian Library in Oxford. Sixty years later the number of courses has risen to reflect the changes in need and the technological advances that make physical presence at a course less necessary. The archive and records management course at SLAIS continues to offer programs to both home and overseas students, and it has developed a research center, ICARUS. Liverpool University Centre for Archive Studies (LUCAS) also undertakes research as well as offering archive and records management courses at both postgraduate and undergraduate levels both on-site and for distance learners, and Aberystwyth University uses the advantage of collaboration with the History and Welsh History Department for the Information Studies programs. The latter offers distance learning options as does the Centre for Archive and Information Studies (CAIS) at the University of Dundee where the centre also caters for family and local historians. The University of Northumbria offers a distance-learning course in records management.

Information management has increasingly been the focus of many of these courses with the development of electronic communications, not the least at Glasgow University where the Humanities Advanced Technology and Information Institute (HATII) was formed in 1997, bringing together expertise in Information Communication and Technology (ICT) in the heritage sector. It offers an MSc in Information Management and Preservation (Digital) and has an extensive research program.

An important link between the universities and the profession is maintained by the accreditation of courses by the Society of Archivists (see below), which also offers additional training and short courses for professional development.

PROFESSIONAL SOCIETIES AND ORGANIZATIONS

The Society of Archivists (<http://www.archives.org.uk/>) was founded in 1947 as the first professional organization

for archivists, and it has grown to include conservators, records managers, and institutional affiliates. It exists to promote the care and preservation of archives and the better administration of archive repositories, to advance the training of its members, and to encourage relevant research and publications. It has a range of benefits for its members, now (2008) nearly 2000, and plays an important role in relation to professional qualifications (see above). It holds an annual conference, has regional representation, and works with other related bodies in promoting archives. Many special interest groups operate under the umbrella of the Society.

The Records Management Society (<http://www.rms-gb.org.uk/>) launched in 1983, recognized the needs of an ever-increasing number of people working in the fields of records and information management, including those who wish to develop new management systems. It supports professionals through sharing expertise and knowledge.

The Institute for Conservation (ICON) (<http://www.icon.org.uk/>) was formed in 2005 from several groups of conservators in all disciplines, including archive conservation. It is the lead body for conservation in the United Kingdom and provides guidance, advocacy, training, and education opportunities, uniting the conservation profession and the wider heritage community.

The National Council on Archives (NCA) (<http://www.ncaonline.org.uk/>) was established in 1988 to bring together the major bodies and organizations, including service providers, users, depositors, and policy makers, across the United Kingdom concerned with archives and their use. It aims to develop consensus on matters of mutual concern and provide an authoritative common voice for the archival community. It encourages and assists the education of the public about archives, and some of its objectives are delivered through the PSQG and the Community Archives Development Group (see above).

The Museums, Libraries and Archives Council (MLA) (<http://www.mla.gov.uk/>) is the designated non-departmental public body with a responsibility for strategic work to promote the role of museums, libraries, and

archives in the United Kingdom and within government programs. It has an importance in bringing the different parts of the heritage sector together to work in partnership rather than in isolation, emphasizing the value of coordination.

CONCLUSION

The twentieth century witnessed the development of the professional care for archives in the United Kingdom, and archive and records management services relevant to communities and individuals. The profession has progressed from one dominated by antiquarians to one which seeks to offer services to users of all kinds, based on the belief of the fundamental right to information. Management of that information is becoming the dominant theme in training archivists and records managers, together with partnership with libraries and museums to provide a stronger and wider platform for the heritage sector. The development of electronic communications will continue to challenge the profession, testing long held principles and offering new ways of delivering services.

FURTHER READING AND INFORMATION

All the organizations mentioned above have Web sites with additional and up-to-date information. In addition, Janet Foster and Julia Sheppard (eds.) *British Archives; A Guide to Archive Resources in the United Kingdom* 4th ed. (Palgrave, 2002) gives useful information about over 1000 archives in the United Kingdom, though current arrangements for access should be checked online or by phone. Online resources for this include the TNA Archon Directory (<http://www.nationalarchives.gov.uk/archon/>). *The Public Record Office 1838–1958* (HMSO 1991) and its subsequent volume *The Public Record Office 1959–1969* (Public Record Office 2000) give extensive details on the organization and its development.

United Kingdom: Libraries and Librarianship

David J. Muddiman

Leeds Metropolitan University, Leeds, U.K.

Abstract

This entry provides an overview of contemporary libraries and librarianship in the United Kingdom. After an introduction which identifies some of the key phases and determinants of library development, separate sections are included which discuss national libraries; public libraries; academic (university) libraries; school and college libraries; special libraries. In each case a basic structural and statistical description is provided, the history of the sector is presented in outline, and current policy issues and concerns are discussed. The entry concludes with an examination of United Kingdom librarianship, its professional associations, and library education and research.

INTRODUCTION

The United Kingdom of Great Britain and Northern Ireland (U.K.) is a parliamentary democracy and constitutional monarchy of, in mid-2007, an estimated 60.95 million people.^[1] The United Kingdom is a permanent member of the UN Security Council; a founding member of NATO and of the (British) Commonwealth; and since 1973 a member of the European Union, although not its economic and monetary union. The centralized governance of the United Kingdom has been recently modified by constitutional reform, which, in 1999, created devolved administration of domestic affairs (including libraries) in Scotland, Wales, and Northern Ireland. The U.K. economy is now overwhelmingly postindustrial with an estimated 80.4% of the labor force employed in services; 18.2% in industry and 1.4% in agriculture. In comparative global terms, the United Kingdom is a prosperous and advanced capitalist democracy with a per capita GDP of \$35,300 in 2007.^[2] However, significantly for libraries, higher level literacy rates in the United Kingdom are relatively low compared with other advanced economies: 16% of adults over 16 years of age have literacy levels equivalent only to those expected in children of 11 years or less.^[3] Also of importance for libraries is the multicultural character of U.K. society. In the 2001 population census 7.9% of Britons described themselves as of minority ethnicity (that is, a category other than “White British” in census returns). London is the most ethnically diverse city in the United Kingdom, with 40% of Londoners belonging to a minority ethnic group.^[4]

The modern history of the United Kingdom is underpinned, on the one hand, by its rise to preeminence as the “first industrial nation” and, on the other, by its maritime dominance which, by the late nineteenth century, had created an empire which covered one-quarter of the Earth’s surface. Since then, two narratives of British

twentieth century history have competed for the attention of historians. The first, an epic chronicle of two world wars and decline of empire, is at first sight of little relevance to libraries—although see the counterarguments made, for example, by G.K. Peatling.^[5] The second—which charts the evolution of modern British society, its transformations of class and culture and the rise and decline of its social institutions—has provided a much firmer context for the historical analysis of library and information services. In particular, the history of the British welfare state, the scrutiny of its character and limitations, and the examination of its more recent partial dismantling provide arguably the most appropriate framework and chronology for understanding modern U.K. library and information services.

This is not to say, however, that the development of libraries in the United Kingdom was entirely dependent on the state. Before the mid-nineteenth century a diverse range of libraries had flowered in Britain in response to the demands of an increasingly literate society, financed by private contributions, subscriptions, and endowments. Libraries of colleges and the ancient universities; religious libraries; scientific and philosophical society libraries; circulating and subscription libraries; mechanics institutes; the library of the British Museum itself (founded in 1753)—all of these amounted to an arguably impressive aggregation which catered for many diverse and specialized needs. However, by 1850 the limitations of these libraries had become clear. On the one hand, they offered uneven and unsystematic provision of knowledge, increasingly inadequate in a modern industrial state becoming conscious of its utility and value. On the other hand, these libraries, in the main, limited their provision to specific client groups or those with the capacity to pay—a situation which became gradually recognized as untenable in a society where universal education, numeracy, and literacy were becoming utilitarian, moral, and spiritual goals.

As a result, the passage of an act enabling the establishment of taxpayer funded public libraries in 1850 (1853 in Scotland and Ireland) was as significant for its symbolic as well as its practical consequences. Between 1850 and 1914, library expansion as a whole in the United Kingdom became more and more dependent on public support, either from local ratepayers (in the case of public libraries) or through central government grants. These years saw the foundation of over 500 public library authorities; the expansion of existing university libraries and six new ones in “civic” universities; a hugely expanded British Museum Library which evolved into a “national” library; and the establishment of the National Library of Wales. Important as such expansion was, it remained however partial and uneven, reflecting local and sectional interests, legislation which was permissive rather than mandatory and in some cases, still, the generosity of benefactors such as Carnegie and Passmore Edwards. Only after the shock of the First World War did the construction of library systems become a truly organized state project; the Kenyon Report of 1927 encouraging their development as an “engine of great potentiality for state welfare.”^[6] Over the next 50 years or so, the United Kingdom, with a great deal of success, attempted to develop comprehensive networks of national, public, academic, and specialist libraries. These were usually locally managed but were often co-ordinated by focused policy networks comprising government advisors and powerful professional groupings such as the Library Association (founded in 1877); Aslib (the Association of Special Libraries and Information Bureaux, founded in 1924), and SCONUL (the Standing Conference on National and University Libraries, founded in 1956). Such governance crystallized in influential policy reports such as those by McColvin on public libraries (1942),^[7] Dainton on national libraries (1969),^[8] and Parry on university libraries (1967),^[9] which determined strategic direction and state funding priorities. These were sometimes linked to formal legislation such as the 1964 Public Libraries Act and the 1972 Act which established the British Library.

By 1979, U.K. library provision was widely admired throughout the world not least because it seemed to combine secure financial support from a social democratic state with a relative autonomy of governance and ethics which minimized direct political interference. However, this U.K. model was not without its critics. Some claimed that U.K. information services were disorganized and uneven, compared, for example with the seemingly comprehensive state scientific and industrial services provided in the USSR.^[10] United Kingdom public library services, others argued, were limited and conservative, focusing on a middle-class clientele and neglecting outreach and other service models which might attract disadvantaged users.^[11] However, since the mid-1980s, critiques such as these have been largely superseded by arguments more sympathetic to Conservative Prime Minister Margaret

Fig. 1 The United Kingdom.

Source: <https://www.cia.gov/library/publications/the-world-fact-book/geos/uk.html> (accessed December 31, 2008).

Thatcher's project of rolling back the U.K. welfare state. The U.K. library sector has become, it is claimed, largely unresponsive to the demands of a dynamic free-market economy which is now linked to the fast developing “information” revolution.^[12] As a consequence, libraries in Britain have been exhorted simultaneously to commercialize their management and marketing and to informatise their services and provision, replacing books and documents

with electronic networks and products. United Kingdom public, academic, national, and special libraries have, as we show in subsequent sections, responded to these pressures with differing strategies and with varying levels of success.

NATIONAL LIBRARIES

The United Kingdom is perhaps unique in possessing three “national” libraries: the British Library (BL); the National Library of Scotland (NLS); and the National Library of Wales (NLW). The British Library is, of course, preeminent among these and is the subject of a separate entry in this encyclopedia (see the entry, “British Library,” p. 677). The library can trace its origins back to 1753 when a library was established in the British Museum based on the bequeathed collections of Sir Hans Sloane; the library subsequently expanded exponentially in Victorian times, especially under the tenure of librarian Antonio Panizzi (Keeper of Printed Books 1837–1856 and Principal Librarian and Director 1856–1866) who oversaw the development of its Bloomsbury site and the famous round reading room. Subsequent developments in the later nineteenth and twentieth centuries saw the foundation of a series of “national” libraries: the Patent Office Library (from 1854); the Science Museum Science Library (from 1883); the Central Library for Students (from 1916 to 1931, after 1931 the National Central Library); and the National Lending Library for Science and Technology (from 1957). The British Library Act of 1972, which created the modern-day BL, effectively unified this by then unwieldy number of national services and collections in science, commerce, reference and interlending. Subsequently the library has rationalized its operations around two locations: its public face at the St Pancras Building in North London, opened in 1998; and its back office and collection storage facilities at Boston Spa, West Yorkshire. The library employs an estimated 2000 staff who operate on resources of approximately £120 million per annum (2007). It maintains collections of approximately 14 million monographs and 880,000 serial titles as well as numerous manuscript, audiovisual and, increasingly, digital sources. (For more detailed statistical information see the separate entry *British Library*.) It is one of six legal deposit libraries in Britain and Ireland (others being the NLS; the NLW; the Bodleian, Oxford University; and Cambridge University Library and Trinity College, Dublin) and is entitled, under the terms of the Legal Deposit Libraries Act (2003) to receive copies of all U.K. publications including, now, certain forms of electronically published material. In line with this, the contemporary BL is strategically committed to expanding its digital presence—in terms of collecting electronic publications; electronic catalogs and access; and digital conservation. In

the era of the World Wide Web, it aims to be a “national library which serves the world.”

The National Libraries of Scotland and Wales might reasonably be said to have less ambitious goals: most significantly since the advent of devolved government in the United Kingdom in 1999 they have become focused on their public role as a focus of Scottish and Welsh national culture. Historically, NLS has a longer lineage: its origins can be traced to the Edinburgh Advocates Library founded in 1682 which in 1709 was given the privilege of legal deposit. Throughout the eighteenth and nineteenth centuries this library was regarded as a national library in all but name—eventually it became one by Act of Parliament in 1925. The modern library is now located in its George IV Bridge Building in Edinburgh with a second site, completed in 1995, at Causewayside, further from the city centre. NLW is, by contrast, a mainly twentieth century institution: it was created by Royal Charter in 1907 and sited, despite opposition from Cardiff, in Aberystwyth, geographically central in Wales but away from its most populous cities. The library is housed in an imposing neo-classical building above the town which was eventually completed in 1965. Like the NLS, it benefited from extensive refurbishment in the 1990s.

Functionally, both libraries are similar in many respects: both are U.K. legal deposit libraries; they have collections of a comparable size (circa 6 million monographs in Wales, 8 million in Scotland); they employ similar numbers of staff (265 in Scotland; 300 in Wales); they operate on comparable budgets—total operating incomes of £13 million in Wales (2006/2007); £12 million in Scotland (2004/2005).^[13,14] Both effectively serve as hybrid regional research and national libraries, balancing the general needs of researchers with a growing awareness of their public function as centers of the printed word in Scotland and Wales. Since 1999, when oversight and funding of each library was transferred to the Scottish and Welsh Executives, respectively, both have adopted strategic plans which highlight this latter role and which stress the promotion of national heritage, languages, and culture.

PUBLIC LIBRARIES

United Kingdom public libraries currently constitute a network of 4657 static and mobile service points, administered by 208 local authorities who are responsible for library provision. The largest public library ranked by book issues is now the Norwich and Norfolk Millennium Library which lends 1.157 million books per year; the busiest library in terms of visits is Birmingham Central Library with 1.564 million visitors. In total, U.K. public libraries issue 315 million books per year (2006/7), a decline of 61 million since 2001/2002; although children’s book issues have remained static over the same period at 90 million per annum. To some extent this decline has

been counterbalanced by an increase in library visits to 337 million per year—a 6% increase on 2001/2002. Many of these extra visitors have undoubtedly been attracted by the establishment of a “People’s Network” of (in the main) free to use Internet points in libraries comprising 41,000 workstations by 2006/2007. Expenditure on public libraries currently amounts to £1157 million per annum and this, despite the People’s Network, has remained largely stable since the advent of the Labour government in 1997. Fifty-five percent of this sum is spent on staff; 12% on books and materials and 33% on buildings, equipment, and other items.^[15] The comparatively low expenditure on books and materials has attracted vociferous criticism in recent years.^[16]

Public libraries in England and Wales are managed within the framework of the 1964 Public Library and Museums Act, which requires that each local library authority provide a “comprehensive and efficient service.” (Scotland has its own public library legislation, most recently the Public Libraries Act (Scotland), 1955). In England, the central government Department for Culture Media and Sport (DCMS) is responsible for ensuring the implementation of the act and through its agency the Museums, Libraries and Archives Council (MLA) it coordinates policy and strategic direction; the Scottish, Welsh and Northern Ireland devolved executives now exercise similar functions in these regions. In recent years DCMS and MLA have tried to bring a degree of consistency to uneven local library services through the introduction of public library standards in 2001. However, these have been subsequently diluted, not least because of lack of clarity regarding the consequences of non-compliance. Perhaps more important has been the policy document *Framework for the Future* (2003) which DCMS heralded as a “long term strategic vision for the public library.”^[17] This tried to resolve, albeit with a mixed degree of success, some of the dilemmas facing the public library in an advanced “information” society (see discussion below).

The history of the U.K. public library movement is now well documented and the facts of public library development are clear enough. The basic picture is one of enabling acts of parliament supported by government enquiries and reports leading to gradual long-term expansion and improvement, albeit punctuated by alternate periods of inertia and reform. The initial public library act of 1850 was sponsored by the utilitarian radical Liverpool MP William Ewart and supported by evidence gathered by Edward Edwards, a British Museum library assistant later to become City Librarian of Manchester. The act permitted any municipal borough with a population above 10,000 to establish a “free” library provided two-thirds of ratepayers supported one, setting a limit on the local tax which could be raised. The first local borough to adopt the act was the city of Norwich (in 1850); although the most important early civic library to be opened was Manchester in 1852, at a ceremony attended

by Dickens, Thackeray, and other distinguished Victorians. Until the 1880s further expansion was slow—by 1886 only 125 authorities had established libraries. After amending legislation in 1886, however, which relaxed the conditions for adoption, new libraries burgeoned, encouraged also by endowments from philanthropists such as Scots-American steel magnate Andrew Carnegie and journal publisher John Passmore Edwards. By 1918, 561 municipal boroughs—the majority—had established libraries, some with a fairly large network of branches.^[18] Subsequent periods of expansion included the 1920s and 1930s, after a 1919 act which enabled rural counties to operate as library authorities and finally the 1960s, when the integrated national library system recommended in the famous McColvin Report of 1942 finally reached near fruition. Arguably the “golden age” of the U.K. public library, the 1960s saw a doubling of real expenditure on the service; the construction of many modern library buildings; the expansion of information, children’s and outreach services, and a rationalization of administration through the creation of larger authorities in England and Wales in a Local Government Act of 1972. Since the 1980s, however, fortunes have been rather more mixed: in common with much of the U.K. welfare state, public libraries have faced expenditure cutbacks, decreasing professional staff numbers and a worrying fall, since the 1990s, in adult (although not children’s) book loans. Nevertheless, public librarians have attempted to innovate through community librarianship and “outreach” initiatives; improving “customer” responsiveness; implementing the aforementioned “People’s Network” and opening some impressive new library buildings—aptly at Norwich, the first U.K. public library authority and more recently in award-winning buildings at Peckham, South London, and Brighton.

Beyond this relatively straightforward narrative of growth and development, however, U.K. public library history is undoubtedly more complex than it first appears. In contrast to its steady material progress, the underlying philosophy and rationale of the public library has always been contested, and an analysis of over 150 years of debate about the purpose and societal impact of the service reveals a series of unresolved tensions at the heart of the public library idea. Perhaps the most fundamental of these were the differences between Benthamite liberals, such as Ewart, who saw libraries primarily as a vehicle for *individual* self-improvement and opportunity, and late Victorian idealists, socialists and even some nationalist conservatives, who emphasized the benefits of the library for *communities* and society as a whole. Many subsequent public library policy debates can be traced back to these differences: the legitimacy of libraries’ leisure role and specifically the “great fiction question” (regarding provision of leisure reading) which surfaced in the 1890s; the debates over provision to, and expenditure on, reluctant, “disadvantaged” and mainly working-class library clients

which began in the 1930s; conflict between “localism” and the perceived need for national structures and standards; tensions, especially from the 1960s onwards, between stock provision driven by reader demand and more culturally conservative collection management policies. Most of these issues have never really been resolved: instead, in the mid-twentieth century years of plenty, public libraries attempted arguably to be all things to all people. Questions of fundamental purpose were certainly sidelined in favor of a functional consensus of “public service,” typified by the 1971 statement of *Public Library Aims and Objectives*, produced by the Public Library Research Group.^[19] This defined public libraries as a “multipurpose information-education-culture agency” and enumerated their objectives under the headings of education; information; culture, and leisure. Most subsequent government policy documents—including the recent *Framework for the Future*^[17] have continued this all inclusive public service convention.

Partly as a consequence of this legacy, twenty-first century public library policy tends to be hampered by unresolved problems of purpose and rationale. These are complicated still further by the onset of the “information” society which has brought with it the informatisation and networking of libraries; new business-led managerial practices; and market-oriented “retail” models of service. Initially, from its inception in the mid-1990s until its near completion in 2004, the key library informatization project—the People’s Network—was heralded optimistically as a “turning point” for the U.K. public library, marking, perhaps, a reconstitution of the “public sphere” in the information society. More latterly, however, and despite the network’s undoubted initial success, such optimism has been replaced by a realization that wiring up the library is perhaps not the panacea it once seemed—especially as home Internet access becomes cheaper and more universal in the United Kingdom (in 2006, 57% of U.K. households had home Internet access).^[20] The focus on the network has consequently dissipated and been superseded by an eclectic mix of ideas and blueprints for the public library’s future. These include the initiatives of radical and “community” librarians who advocate refocusing the service around literacy, community engagement and social inclusion; the visions of “modernizers” who want to reinvent public libraries as centers of new digital technologies and rebrand them as “Idea Stores” or “Discovery Centers”; and the arguments of traditionalists who favor a “back to basics” approach of restoring expenditure on books and a return to the core purpose of book provision, linked usually to a retail led strategy of improved marketing and promotion. The impact of such competing ideas—none of them dominant—is difficult to gauge. However, in a climate of financial pressures, falling book issues and the disaggregation of U.K. local government, the clamor for urgent and sometimes contradictory action has undoubtedly engendered a sense

of uncertainty and insecurity in public library circles. Perhaps it is finally the case that the public service consensus, which has sustained British public libraries over the last century or so, is beginning to dissolve.

ACADEMIC LIBRARIES

In the United Kingdom, libraries in universities and colleges of higher education (commonly known as “academic” libraries) now operate within a unified framework of state higher education created in Education Reform Acts of 1988 and 1992. (In the United Kingdom “higher” education is defined as degree or diploma level education targeted at students of 18 years old or over.) They are funded in the main through their parent universities or colleges, which receive most of their income in turn from block grants made by regional funding councils (for England, Wales, Scotland, and Northern Ireland) and student tuition fees. Academic libraries provide services in a total of 168 higher education institutions, 106 of them universities and the remainder colleges of higher education. They serve an estimated total of 2.34 million students (1.79 million undergraduates, the remainder postgraduate) and 165,000 academic staff; total higher education library expenditure amounted to £561million in academic year 2005–2006. Within these institutions there are a total of 864 separate academic library service points employing in 2007 10,565 staff, 3979 of them professional, the majority of the latter being members of CILIP.^[15]^[21] Collectively, U.K. academic libraries are represented by the Society of College, National and University Libraries (SCONUL) which serves as a forum and lobbying body for the whole sector. In addition, Research Libraries UK (formerly CURL, the Consortium of University Research Libraries) performs a similar function reflecting the interests of 25 leading university research libraries, together with Britain’s national libraries and the Victoria and Albert Museum.

United Kingdom academic libraries have, of course, a long heritage dating back to the foundation of the medieval universities in the late thirteenth and fourteenth centuries. Recognizable university libraries were established at Oxford in 1412; Cambridge in 1424; St Andrews in 1411, and Glasgow in 1451, although collections of donated books in particular colleges predate these. Subsequent development of university libraries progressed unevenly, although major advances paralleled the proliferation of the printed book in the late Tudor period and saw the expansion of Cambridge University Library, the establishment of Edinburgh (1580) and the foundation of the Bodleian Library at Oxford (1602). It was not, however, until after 1750 that these libraries really began to resemble the familiar institutions of today: the century after that date witnessed, often for the first time, reader access to shelves; transparent catalogs, and skilled librarians. By 1849 the

Bodleian, for example, comprised 220,000 printed volumes and 21,000 manuscripts compared with only 30,000 volumes and 6000 manuscripts, respectively, in 1714.^[22] By then, moreover, the medieval universities had been joined by new universities in London and Durham each of which began to develop library systems. Perhaps even more significantly, by the end of the nineteenth century, libraries were being established at several new “civic” universities and colleges in Britain’s major cities, many of them with a scientific and technical bias. By 1925, 13 such institutions were operating, most of them funded by the British state, which had established a University Grants Committee (UGC) in 1919.

Between 1930 and 1960 academic library development continued piecemeal, although some impressive buildings, such as the Brotherton Library at Leeds (see Fig. 2) date from this time. Although library services gradually became professionalized (SCONUL was founded in 1956) and libraries were developed as the number of colleges and universities grew, there was little uniformity in the resources which parent institutions granted to libraries, or in the services and priorities of the libraries themselves. Two key developments of the 1960s changed matters. The first, a report for the UGC subsequently known as The Parry Report (1967), recommended a number of minimum standards for academic libraries including the principle that universities should devote “about six percent” of their budget to library provision, and these were broadly accepted. The second, the creation first of a group of new elite universities and, more widely, of a large number of vocationally oriented “polytechnics” with degree awarding powers, spawned the development of a large

number of new libraries in higher education, establishing the service structures still in place today. Library development between 1970 and 1992 subsequently coalesced around two broad models:

- An academic/research model which prioritized collection development and management and was mainly adopted by larger, older, and elite universities with substantial research resources (many of these libraries founded CURL in 1983).
- A teaching and learning library model which focused on currency of resources and renewal of stock together with undergraduate student needs and user education. This model was largely adopted in polytechnics, colleges of higher education, and some smaller “modern” universities.

In many ways, of course, contemporary adaptations of these models of academic library provision still persist. However, arguably since 1992 when the United Kingdom moved to a uniform system of HE, the direction of academic library policy has been instead dictated by a new educational paradigm of massified, and more latterly networked, higher education. In 1988/1989 U.K. universities enrolled 517,000 undergraduate students. By 2005/2006 this figure was 1.79 million.^[21] The Universities Funding Council commissioned Follett Report (1993) heralded a period of unprecedented change for academic libraries as they adapted, in the main very positively, to this new environment. Following Follett, the new post-1992 Higher Education Funding Councils (for England,

Fig. 2 The magnificent interior of the Brotherton Library, University of Leeds. Opened in 1936, the central rotunda consciously imitates the famous British Museum Library reading room.

Source: University of Leeds.

Scotland, Wales, and Northern Ireland) together provided over £140 million which was spent on over 100 new building developments. Even more significantly for the future, through the Funding Councils' Joint Information Systems Committee (JISC, established in 1993), Follett inaugurated the so-called E-Lib program in which a £15 million budget contributed to over 60 developmental ICT projects in fields such as electronic journals; digitization of catalogs and source material; online publishing and electronic document delivery.

After the completion of E-Lib in 2001 and the concurrent stabilization of networked technologies around the World Wide Web, many U.K. academic libraries moved rapidly to a "hybrid library" model of complementary electronic and print-on-paper services. Such moves were often accelerated by the convergence of library management with that of ICT and media resources across whole institutions, together with, since 2003/2004 the adoption by many universities of virtual learning systems such as WebCT or Blackboard. Spurred on by these developments, some academic librarians have become especially focused upon the theory and practice of information literacy, SCONUL itself developing the now ubiquitous "seven pillars" approach to student information skills. According to SCONUL, U.K. academic libraries over the next 10 years are likely to become increasingly personalized and customer focused and be characterized by "complex blended systems" and multiuse, multipurpose buildings.^[23] While many influential U.K. academic librarians actively embrace this vision of flux and change, others urge caution at such "postmodern" approaches, worrying openly about the custodial and collection management role of the university library, the decline of scholarly research and authoritative published knowledge.^[24] Such tensions, perhaps, together with the consolidation of interest groupings such as Research Libraries UK, suggest that the character of U.K. academic libraries (like higher education itself) may become increasingly heterogeneous and diverse.

SCHOOLS, COLLEGES, AND SERVICES TO CHILDREN

Colleges of Further Education

Although many of the United Kingdom's universities have now developed a focus on technical and vocational qualifications, the bedrock of U.K. provision in this field is a network of 495 Further Education (FE) Colleges. These colleges offer a range of subdegree qualifications to students aged 16 years and over; a few also offer higher level qualifications such as "Foundation" degrees in collaboration with local universities. Most of the colleges were established in the 1950s and 1960s: initially they were administered by local education authorities; however,

following the reorganization of the sector in 1992 they are now corporate bodies overseen and funded by a Learning and Skills Council (in England) and similar bodies in the rest of the United Kingdom. All of the colleges have developed libraries serving the needs of staff and students but these vary considerably from college to college: there are no statutory requirements regarding service levels, although colleges are subject to an inspection regime overseen by OFSTED (the U.K. Office for Standards in Education) which includes scrutiny of learning resource standards. Consequently, some colleges and their librarians have developed innovative, well resourced learning resource centers which characteristically locate the library at the center of the college managed and virtual learning environment. At the other extreme, however, some college library services are undoubtedly under-resourced, marginalized and lacking in professional library staff. The most recent CILIP survey in 2003^[25] found, for example, that only 7.2% of college libraries received over 1% of the college budget and that several small colleges (those with less than 8000 students) were operating without qualified library staff. The median number of professional staff in these small colleges was one; in medium colleges (8000–18,000 students) it was two and in large colleges of over 18,000 students, four. Notwithstanding such problems, however, many U.K. FE college librarians maintain a vigorous commitment to modernizing and improving services in the field. They are represented by the CoFHE group of CILIP (which produces important guidance on standards and good practice)^[26] and the Council for Learning Resources in Colleges (CoLRiC) which acts as a lobby group for the enhancement and improvement of services.

School Libraries

Libraries in U.K. schools have, of course, a much longer heritage than those in FE colleges. Some English grammar schools began to develop systematic collections of books in the sixteenth century and by the late seventeenth century several of these schools had relatively large libraries of a few hundred books or more with written rules and designated masters in charge.^[27] However, it was not until the early twentieth century that school libraries began to appear in publicly funded schools: in 1906 the U.K. Board of Education stipulated that every new secondary school (for pupils aged 11 and over) should keep a library. Subsequent progress was slow—in 1936 the Carnegie United Kingdom Trust reported uneven and largely poor school library provision, a situation that only gradually improved before the 1970s. By then, school libraries had become almost universal in secondary schools and most local education authorities (LEAs) in addition funded school library support services which provided materials and professional advice for libraries in both secondary and primary (elementary) schools. By this time also, school librarianship in the United Kingdom had become organized

professionally, the Library Association maintaining a specialist School Libraries Group and a separate School Library Association (SLA—founded in 1937) attracting the support of interested teachers and teacher-librarians. Both of these organizations acted as foci for progress and innovation, producing journals which disseminated good practice together with standards and guidelines. Spurred on by such activity, the 1970s and 1980s were, by and large, decades of expansion and improvement in school library services, especially through the development of integrated school resource centers and quality provision of book stock. Some local education authorities, such as Nottinghamshire and the Inner London Education Authority (both of which appointed qualified librarians in all secondary schools), were at the forefront of these innovations.

Since 1990, however, it is generally the case that the progress made toward universal high quality school library provision has been complicated if not reversed. In spite of pressure from the LA (more latterly CILIP) and the SLA, and in part because of continuing tensions between them, the issue of professional staffing in school libraries has never been resolved: the most recent survey by CILIP (2002) estimates that only 30% of the 4000 or so secondary school libraries in the United Kingdom are managed by a chartered librarian; 20% are run by teachers or teacher librarians; and the remaining 50% by library assistants or others.^[28] Moreover, local management of school budgets, introduced in 1990, has severely affected the stability and effectiveness of LEA school library support services: these services no longer receive direct funding from LEAs but instead enter into contractual agreements with individual schools who “purchase” their services and are no longer required to use them. Some schools have consequently opted out of this provision—the most recent figures estimate that 15/193 LEA support services have been forced to close since 2000–2001 and that they now serve only 82% of primary school children compared with 90% at that time.^[15] In spite of these difficulties, however, expenditure on school library services as a whole has been maintained roughly in line with inflation (a total spend of £39 million or £1.85 per pupil in 2005/2006) and U.K. school librarianship as a professional activity continues to thrive. Many schools have developed model services and initiatives in fields such as reading and literacy; information skills; materials selection; special needs provision; and children’s access to and use of the World Wide Web. Many of these new developments are embedded in CILIP’s *Guidelines for Secondary School Libraries* (2004) and *The Primary School Library Guidelines* (2002).^[29,30]

Public Library Services to Children

Closely linked to school library support services in many areas of the United Kingdom are children’s departments of public libraries: both are operated by local authorities and

often share a number of professional and administrative functions. Unlike schools, however, public libraries are legally obliged to provide children’s services by the 1964 Public Libraries Act. As on March 31, 2006 they held 25.3 million children’s books, equivalent to 2.3 per child, and they spent approximately £50 million per annum on the service. United Kingdom public libraries are estimated as employing approximately 600 FTE professional children’s librarians, with a further 100 employed in shared posts with schools services. In 2005/2006 they loaned approximately 90 million books, a figure which, unlike its adult counterpart, is rising again at a rate of 4% per annum after falls in the 1980s and 1990s. An estimated 55% of U.K. children aged 0–14 are registered members of public libraries.^[31]

Children’s public libraries in the United Kingdom date back almost to the inception of the public library itself—Manchester Public Library opened a separate room (for boys) in 1861 and in 1871 Birmingham Public Library recorded a collection of 456 books for children.^[32] However, subsequent development of children’s services was uneven, although the decade before World War I (when many separate children’s collections were first established) and 1925–1939 (when children’s librarianship as a distinct profession emerged) marked significant advances. It was not until the late 1960s and 1970s, however, that services experienced major advance. Underpinned by the statutory force of the 1964 Act, fueled by a quantum leap in both the quantity and quality of children’s books and inspired by classic professional texts such as Janet Hill’s *Children are People* (1973),^[33] children’s librarianship became arguably the most proactive, creative, and successful component of U.K. public library provision. Since then children’s librarians have played a leading part in developments such as outreach, services to teenagers, ethnic minorities, and children with special needs; they have engaged in literacy and more latterly information literacy work—the latter especially in conjunction with the establishment since 2000 of the “People’s Network” in the public library. Since 1997 children’s libraries have also become important in a number of the Labour government’s multiagency “social inclusion” initiatives—the most significant of these perhaps being “Bookstart” (and its successor “Surestart”), a literacy and social care initiative targeted at children under 5 years of age and offered now in 85% of U.K. local authorities. In part because of work such as this, children’s services tend to have avoided much of the uncertainty of purpose which has dogged the rest of the U.K. public library movement. Despite recurring problems of funding, management, and inconsistency in service levels, children’s services in general enjoy the rhetorical support of policymakers because of their clear educational focus and relevance to literacy. There is, moreover, general professional agreement on a strategy for developing children’s libraries—embodied in the policy document *Start with the Child* (2002) this proposes a program of innovation and

diversification of provision in response to new media and the changing culture and needs of children.^[34] Access to resources to fully implement such plans, however, continues to be problematic.

SPECIAL LIBRARIES

Specialist information provision in the United Kingdom is now, as one would anticipate in any advanced post-industrial society, kaleidoscopic in its subject range and heterogeneous in its institutional arrangements. The current *ASLIB Directory of Information Sources in the United Kingdom* lists over 10,700 organizational repositories of information: only a minority of these are obviously libraries.^[35] However, special *libraries*, in the sense of collections and services in limited subject fields, and more especially “workplace” libraries, serving distinct groups of occupational and institutional users, clearly still constitute an important subsection of this specialist information landscape. Some of these employ large numbers of people in complex organizational settings—the BBC Information and Archives Department, for example, having a staff of over 600^[36]—whereas many services in small companies and voluntary organizations are operated by lone librarians. The extent of special library provision is, of course, notoriously difficult to map, but the most recent reliable U.K. survey data, recorded in 1998–2002 suggests a distribution by sector as in Table 1.

Significant specialist areas absent from this survey include libraries in the National Health Service (an estimated 375 libraries in 2002);^[38] news, media, and publishing (an estimated 80 media organizations with libraries in 2008);^[39] and industrial sectors beyond energy and pharmaceuticals. All in all, an informed estimate would probably gauge that around 5000 specialist information units which are recognizable as libraries currently operate in the United Kingdom: this figure roughly tallies with CILIP estimates of approximately 4000 professional members working in the special libraries sector (see section “U.K. Library and Information Profession”). However, as we

shall see, some sectors, such as commercial, industrial, and media libraries, have been subject in the past few years to closure, contraction, or drastic organizational change, whereas others, such as libraries in health and other government services, appear to be consolidating around new “hybrid” models of service provision.

The first genuine examples of specialist library provision in the United Kingdom are generally held to have been founded in the early modern period, although arguably some collections (such as, for example, those of medieval monasteries) predate these. The institutions of the traditional professions—medicine, law, and the church—tended to develop libraries from the mid-sixteenth century onward, such as those in the Royal College of Physicians and the Inns of Court in London. The scientific revolution of the seventeenth and eighteenth centuries subsequently underpinned the foundation of important libraries such as those of the Royal Society (1666) and a number of provincial and specialist scientific societies; the increasing reliance of government on knowledge and information also began to be acknowledged through the creation of the Foreign Office Library (1801) and the House of Commons Library (1818). However, it was not until the second part of the nineteenth century that special libraries began to noticeably proliferate in significant numbers. Impelled by a cluster of societal forces linked to accelerating modernity—the increasing specialization of knowledge; the diffusion of knowledge reliant industries; the rise of professional occupations; the expansion of the state and its bureaucracy; the invention of new information and communication technologies—libraries and information or “intelligence” bureaux of diverse kinds began to penetrate the United Kingdom’s governance and economy. By the 1920s, large industrial concerns such as Metropolitan Vickers in Manchester and Rowntree in York had established libraries linked to sophisticated research and intelligence centers; the state itself also began to fund technical libraries in “Research Associations” linked to specialist industrial sectors. In 1924 a grouping of 84 such public and private sector concerns organized themselves in ASLIB—the Association of Special Libraries and Information Bureaux—an umbrella group which acted less as a professional association than a “clearing house” for an envisaged national network of specialized information services. From 1944 ASLIB attracted state funding to further this goal; by 1960 it had 2500 corporate members, processed a workload of 35,000 enquires per annum; employed over 40 staff and supported a prestigious research department.^[40] By this time, specialized library and information networks in most of the sectors enumerated above had been established along lines that are recognizable today: central government libraries expanded enormously in the three decades after World War II (for example, the Board of Trade Library in 1950 had a staff of 40 with one professional librarian; by 1976 this had grown to 147 staff with 46 librarians^[41]) and, by

Table 1 Distribution of U.K. special libraries by workplace sector (1998).

Sector	Number of libraries
Government departments	60
Other government organizations	379
Voluntary agencies	1390
Professional societies, etc.	210
Legal	1400
Commercial; financial	211
Energy	83
Pharmaceuticals	93
Management/information consultants	200

1972, a survey estimated that 1182 industrial and commercial libraries were operating in Britain.^[42] Most of these libraries by the 1970s offered a proactive information service to their users. This generally included the use of the techniques of documentation pioneered in Britain by S.C. Bradford and others in the mid-twentieth century, and it supplemented the traditional librarian's function of the collection and organization of information with techniques of analysis and dissemination. Some of this work became professionally recognized as "information science" in the 1960s and 1970s, specifically through the foundation (in 1958) of the Institute of Information Scientists (IIS), an organization which had 750 members by 1970.^[40] By comparison, "special librarianship" in Britain, in contrast to the United States, never convincingly evolved as a specialist profession, although the U.K. Library Association did set up a rather poorly supported Reference, Special and Information Section in 1949.

All in all, by the mid-1970s, the United Kingdom could boast a relatively well-developed and well-organized network of specialist library and information provision, in part supported by the state through ASLIB grants and other mechanisms of arms-length subsidy. Over the next 30 years, however, this system of state-sponsored pluralism would in large part fragment as a result of the economic, technological, and political transformations linked to postindustrialism. In the commercial and industrial sectors, many hitherto site-specific libraries, especially those in large companies, were restructured or downsized as a result of accelerating globalization and corporate realignment. In the public (state) sector similar upheavals were experienced in the wake of the privatization, between 1979 and 1997, of large state utilities such as energy, water, coal, steel, telecoms, and railways. Even libraries in government departments themselves, and those in state-funded services such as health, underwent a commercialization of sorts through the introduction of private sector management regimes such as cost-benefit analysis; market testing and performance measurement—procedures which became ubiquitous in all United Kingdom special libraries by the end of the century. Linked to, and facilitating, many of these trends was the information technology revolution: especially the advent of organizational intranets from the late 1980s and the Internet from the late 1990s onward. These technical changes heralded a major transformation of the structures, functions and scope of United Kingdom special library and information services. On the one hand, they seemed to promise a prominent role for library and information services in the exploitation of a newly recognized and valued commodity; on the other, they threatened the potential extinction of the "library" and the special librarian and their replacement by the database, the World Wide Web and the intelligent network.

At the present time many of these transformations are still incomplete; however, what is clear is that the shift to a postindustrial political economy has had an uneven impact

on the United Kingdom's special library networks. ASLIB has contracted, losing its government funding in the late 1970s and transforming itself into a commercially focused "Association for Information Management" in 1983, offering information consultancy services, training and publishing to an international market. (ASLIB finally abandoned its charitable status in 2004 and now operates on full commercial lines. It currently has a corporate membership of approximately 380 members.^[43]) Some special library sectors have similarly suffered: in news and media provision an almost complete revolution appears to have been effected since 1998 with the traditional "cuttings" service being completely replaced by digital systems where editorial staff have direct access to electronic data and records.^[36] Other service sectors, however, such as health, legal information, and voluntary agencies have witnessed a proliferation of small library and information units as the importance of information has come to be acknowledged in, for example, medium-sized law firms and headquarters of charities. More traditionally run library services, such as those in central government and professional and learned bodies, have typically contracted in size and been forced to change, but they have in the main retained their institutional integrity. Even in these cases, however, a constant theme—not unique to the United Kingdom—has been modernization: the challenge faced by specialist librarians to establish a new role for themselves and their libraries in the face of constant organizational and technical change. Consequently, most special libraries in the United Kingdom now transparently operate in a "hybrid" library environment, coupling traditional elements of document based provision—needs assessment; current awareness; collection management; enquiry work—with an increasing focus on the creation, organization, and accessing of digital resources and the "digital consumer." As their parent organizations inexorably move toward an integrated digital environment it seems likely that the specialist information professionals of the future will gradually supplant their traditional "intermediary" role with a broader remit for organizational information resources, encompassing new functions such as internal records management, digital archiving, information auditing, and knowledge capture. Whether or not this new aggregation of professional work—variously labeled "information"; "knowledge" or "records" management—will result in the salvation or the demise of the special library, remains, of course, to be seen.

THE U.K. LIBRARY AND INFORMATION PROFESSIONS

The Workforce

According to the most authoritative current estimate, the total U.K. library and information workforce comprises

61,230 employees as at mid-2005.^[44] Fifty-eight percent of these employees are estimated to be female, 42% male; 52% work full-time, 48% part-time. These figures include 21,691 full-time equivalent posts in public libraries, 9470 in academic and school libraries, and 2252 in the British Library and other national libraries. In public libraries an estimated 23% of posts are of professional level; in academic libraries the proportion is a predictably higher one of 34% and in national libraries 41%. Recent trends indicate a marked decline by 5% since the year 2000 of professional posts in public libraries; however, this is counterbalanced by a similar rise in the professionalized workforce in academic libraries. The extent of professionalization in the wider information sector—business, industrial, voluntary, and other specialized information services is unclear. However, CILIP (see below) in 2003 reported 1737 members working in industry and commerce; 746 in medicine and health; 1066 in specialist government libraries; and 288 as independent consultants.^[45] This amounts to a total of approximately 4000 members, or 25% of the institute's membership.

CILIP

CILIP, the Chartered Institute of Information and Library Professionals, is the main U.K. body representing this librarianship and information science (LIS) workforce. CILIP was inaugurated only relatively recently on April 1, 2002 as the result of a merger between the former Library Association and the Institute of Information Scientists. It is governed on democratic principles with an elected President and Council of Trustees, although in practice the permanent Chief Executive (currently Bob McKee) is perhaps the most influential figure in its management and strategic direction. CILIP is organized into 12 regional branches including CILIP in Scotland (Slainte), Wales, and Ireland—entities which effectively superseded partly autonomous library associations there. Its membership currently stands at 21,000^[46] and is drawn almost equally from public libraries (24%) academic and school libraries (24%) and specialist information services (25%); the remainder comprising members in national libraries (3%) and overseas, retired, and student members.^[45] The main level of membership within the Institute is that of chartered member (MCLIP) which is the basic professional credential in U.K. information work. Through CILIP's recently approved Framework of Qualifications this is now complemented by the award of fellow (FCLIP) for excellence in professional achievement and certified affiliate (ACLIP), an award which accredits achievement and experience among paraprofessional workers.

In addition to these core membership functions, CILIP undertakes a very wide range of activities which belie its relatively small size and resources. As well as the aforementioned regional branches, the Institute supports 29 specialist interest groups which range across the spectra

of library and information science and management, and many of these groups sponsor world class journals, conferences, and professional training. CILIP maintains a publishing arm (Facet Publications) which produces leading research monographs, textbooks, and handbooks. It also publishes *Library and Information Update*, the key monthly newsletter and review of the U.K. library and information community and it organizes a regular program of training, conferences, and professional development events. CILIP's work in policy and advocacy (see also below) is also becoming increasingly important, focusing currently on aspects of information society policy such as copyright and legal matters; social inclusion; information literacy; equal opportunities; and economic development. Some of this policy work can be seen to be of international significance: CILIP's *Ethical Principles and Code of Professional Practice*, for example, serving as a model for many LIS organizations worldwide. International work more generally continues through CILIP's numerous links with IFLA and its efforts to bring an LIS professional influence to bear on global informational developments, for example through input to the UNESCO World Summit on the Information Society.

History of the Library and Information Professions

The professionalization of library and information work in the United Kingdom is linked to the establishment and evolution of a number of professional groupings in the century between 1870 and 1970. Although most of these groupings are now unified under the umbrella of CILIP, this has not always been the case. The largest and most important of these, the Library Association (LA), was founded in 1877, one year after its American equivalent and arguably as a direct consequence of the impact of the latter's inaugural meeting. Although the LA's initial objectives were impressively broad—"to unite all persons engaged in or interested in library work for the purpose of promoting the best possible administration of existing libraries and the formation of new ones where desirable"—during its first 50 years the association proved itself rather exclusive. True, it was in 1898 granted a Royal Charter and the right to award professional qualifications. By 1899 it had also created what proved to be the seminal journal in early twentieth century librarianship—the *Library Association Record*. However, its leaders—initially until 1895 a group of eminent bookmen and bibliographers, and after that a succession of leading public librarians such as Duff Brown, Jast, and Berwick Sayers—were arguably overly concerned with status, professional standards, and policy lobbying. Membership matters were certainly neglected. Little was done to encourage the bulk of library staff—library assistants—to support the association; they formed a separate Library Assistants' Association (LAA) in 1895. Moreover, the perceived public

library bias of the LA deterred potential members in universities and special libraries. By 1928 membership stood at a disappointing 897 members, a situation which set limits on both the influence and range of activities of the association.^[47]

During the 1930s, however, reforms largely associated with Ernest A. Savage (Hon. Secretary of the LA, 1928–1934) and Lionel R. McColvin (Hon. Secretary 1934–51) expanded both the LA's membership base and its range of professional activities. The Association of Assistant Librarians (formerly the LAA) became a section of the LA in 1930 and some formerly independent regional groupings became branches. A logically planned structure of specialist interest sections and regional branches was established. Money was obtained from the Carnegie United Kingdom Trust and the Rockefeller Foundation to establish a professionally staffed headquarters and information service. A public profile, typified by the inauguration of awards like the Carnegie Medal for Children's Literature in 1936, was established. By 1939, membership had risen to over 6000 and although World War II brought a pause, expansion resumed in the 1950s and 1960s. The establishment of permanent schools of librarianship in Colleges of Advanced Education and later universities, together with the reform and streamlining of the LA's own associateship regulations and examinations, ensured a steady supply of new members. The proliferation of public, academic, and public sector specialist libraries, in what would prove to be the heyday of the British welfare state, provided ready employment for them. By 1965, LA membership exceeded 15,000; by 1980, 3 years after its centenary year, it had reached 25,000, its historic peak.^[48] By this time the LA had become a sophisticated, multifaceted modern bureaucracy which, despite periodic complaints of members, operated effectively and by and large on democratic lines. Its range of functions—course accreditation; conferences; training; publishing; professional advice; international work; policy development and lobbying; continuing professional development—typified those of a progressive professional body. Most would be familiar to observers of post-2002 CILIP.

Despite these advances, the impression (some would argue misplaced) that the LA was, at root, a public library association continued to persist. Although academic and school librarians did join in increasing numbers after 1950, and although specialist LA interest groups were formed, these specialisms in the end found it necessary to organize professionally outside the association in the guise of the School Library Association (formed in 1937) and SCONUL (formed in 1956—see the sections on School Libraries and Academic Libraries). More importantly still, despite the creation of successive Reference, Special and Information Sections from the 1950s onward, the LA continued to find it difficult to recruit members from industrial, technical, and commercial libraries. In part this was due to the continuing growth of ASLIB (see section

“Special Libraries”), which despite its corporate membership structure in effect functioned very much as a professional forum for these librarians until the 1970s. In part also, this schism was based on the developing contention in the 1940s and 1950s that “documentation” and, more latterly, “information science” was a distinct and arguably more sophisticated occupation than librarianship. Such ideas were to result in 1958 in the foundation of the U.K. Institute of Information Scientists (IIS) by a group of scientific and industrial information officers led by Jason Farradane, a Scientific Information Officer then employed by the Tate and Lyle Sugar Company. Led by Farradane (who moved on to an academic career) the Institute successfully sponsored the development of a number of degree courses in Information Science in the late 1960s and 1970s. This academic ethos subsequently attracted a good number of intellectuals and researchers in information related fields to its ranks, ensuring that it attained a certain prestige and influence, especially in professional education and publication (see also below). It never, however, became a mass membership association, even after the perceived expansion of information work as an occupation in the 1980s. In 1970 it had 750 members;^[40] at its dissolution in 2002 this figure was 2200.^[49]

Since 1980, the steady growth of the U.K. library and information profession has given way to a more turbulent environment associated with the so-called “information revolution.” Although some commentators conjectured that librarianship would prosper in emerging information-work employment markets, it quickly became apparent that the challenges of a shifting “postprofessional” information landscape potentially outweighed the benefits. Some traditional librarianship tasks, and posts, were rendered obsolete by technical change. Cutbacks in (especially professional) posts in the U.K. public sector, especially during the tenure of the Conservative government of 1979–1997, eroded the LA's core employee base; moreover some employers in public and academic libraries began to question the need for professional librarianship credentials and “open up” library posts to applicants with generic IT; management, and business skills. In specialist and commercial fields, new competitors (computer professionals; systems specialists; information and knowledge managers) emerged to claim that they, and not librarians or information scientists, were experts in the handling of information. As a result of these pressures, LA membership fell into gentle, although not catastrophic, decline; IIS membership stalled, failing to grasp the potential (as some saw it) of the proliferation of “information” work.

The U.K. library and information profession's response to this was, as we have seen above, one of rationalization, merger, and the formation of CILIP in 2002. Such a merger had been mooted since the mid-1980s by influential establishment figures such as Wilfred Saunders, who in his *Towards a Unified Professional Organisation for Library and Information Science and Services* (1989)

argued for a federation of the LA, the IIS, and ASLIB as the most effective strategy of competing in the new professional environment. Most commentators, and indeed association members, accepted such rationalization as sensible and inevitable, although in the event ASLIB remained outside the arrangement, pursuing a path of corporate consultancy, publication and training and commercial governance (see section “Special Libraries”). In the 6 years since its creation CILIP, as we have seen, has undoubtedly consolidated its respected public profile as the United Kingdom’s leading information work (as opposed to information technology) professional grouping, although its influence with government, and more especially the private sector, remains uneven. Tensions, too, persist between its disparate occupational sections and, perhaps more significantly, between its professional traditions of rigorous accreditation and occupational control and the need now to compete for members in a fluid and deregulated neo-liberal occupational environment. The ability of CILIP to successfully resolve some of these issues will, to a large degree, determine the nature and extent of professionalization in the United Kingdom library and information workforce in the decades to come.

LIBRARIANSHIP AND INFORMATION SCIENCE— EDUCATION, TRAINING, AND RESEARCH

Closely linked to the evolution of U.K. professional associations was the development of training and education for the nascent U.K. library occupations. Between 1898, when it received its Royal Charter, and 1939, the LA laid down and incrementally improved an examination system linked to a register of professional members. This established the basic standards and structure of professional librarianship in the United Kingdom, comprising “associates” and “fellows” who were both classed as chartered LA members. Students prepared themselves for these examinations through a mixture of part-time classes, summer schools, and a correspondence course operated from the 1920s onward by the Library Assistants’ Association. Examination syllabi consisted largely of “practical” topics: library administration; bibliography; cataloging, and classification, but knowledge of (initially) English literature was tested. (Eventually this was replaced by a paper allowing candidates to specialize in a choice of “information sources” options.) University College London School of Librarianship, founded in 1919, constituted the one exception to this professional monopoly of library education: by the 1930s, under its charismatic head E. A. Baker, it offered a 2 year diploma and 1 year postgraduate course as an alternative to LA examinations. Both of these were broader in scope and more critical and theoretical than the LA scheme.

By 1945, however, it had become clear that the prewar system of professional preparation was inadequate in

meeting the needs of an expanding labor market: although the LA had 6510 members by then only 1617 of these were qualified/chartered.^[50] Consequently, in the wake of recommendations in the McColvin Report, the United Kingdom finally embarked upon establishing a national system of library education based in universities and colleges. At first, between 1945 and 1955, schools of librarianship were created in nine technical and commercial colleges in major British cities; these schools prepared students for a reformed LA diploma, and after 1966 for degrees awarded by the Council for National Academic Awards (CNAA). In the 1960s, they were joined by six university departments offering degrees and postgraduate diplomas validated and examined internally. Traditional LA examinations continued throughout this time, but they gradually diminished in popularity and were discontinued in 1985. The LA, by now joined by the IIS, gradually became in effect an accrediting body for courses rather than an examining body. However, in membership terms it reaped the reward of this expanded system: by 1972 its chartered members numbered 12,988.^[50] By 1980, the first edition of the student guide *Which Library School* listed 16 U.K. schools of library and information studies providing 24 undergraduate degrees and 17 postgraduate diplomas and masters’ awards. Librarians and information scientists were finally becoming a graduate profession.

One major consequence of this expanded system of training and education was blossoming in the United Kingdom of the academic disciplines of librarianship and, a little later, information science. Before 1939, theoretical writing and research activities in the library and documentation fields had been limited to intellectual “scholar” librarians such as Duff Brown; Jast; Baker, and Bradford. However, with the advent in the 1950s and 1960s of full-time professional employment in library education, the main dimensions of a British interpretation of both librarianship and information science began to be laid down. Raymond Irwin, head of the UCL school, set out the main features of U.K. “librarianship” (which he contrasted to U.S. “library science”) in his *Librarianship: Essays in Applied Bibliography* (1949); Bradford did the same in his *Documentation* (1948). Gradually, in the 1950s and 1960s, an accepted “core” librarianship curriculum emerged comprising applied bibliography; cataloging and indexing; library management; libraries in society: a subject structure reflected in the revised Library Association examination syllabus of 1964. Farradane, Saunders, Vickery, and other information scientists developed an “information science” variant of this in the late 1960s and 1970s, codified in the *Criteria for Courses in Information Science* approved by the IIS. Academic journals, such as the *Journal of Documentation* (established 1945) and the *Journal of Librarianship* (1969), further underpinned these developing disciplines and in the 1960s LIS education began to be supplemented by consistent and professional research activity in the field. Some schools of LIS,

such as the postgraduate school at Sheffield and the large department at the Polytechnic of North London developed a major research focus, although they never attained a monopoly of LIS research: important centers elsewhere in the professional LIS community, such as the ASLIB Research Department, saw to that. Nevertheless, research in the field had become sufficiently legitimized for funding to be provided between 1964 and 1973 by the U.K. government Office of Scientific and Technical Information (OSTI) and after that, with an expanded remit, by the British Library Research and Development Department (BLRDD). The era of the BLRDD (1974–1999), a government agency with dedicated research funding for libraries, had few parallels elsewhere. In 1975–1976, its most generously funded year, BLRDD distributed £1.1 million in LIS research funding and, although its inflation adjusted grant declined after that, it still accounted for 46% of total LIS research funding in 1985. It supported a very wide range of projects ranging from information storage and retrieval through to public, academic, and school libraries and professional education itself. Overall, between 1975 and 1988 BLRDD funded 712 LIS research projects, 29% of them based in schools of LIS.^[51] This represented arguably a golden age in U.K. LIS research.

By 1980, LIS and its associated education and training programs in the United Kingdom arguably constituted a classic public service formation—comprising the state as educator and main employer; the professional bodies and the academy. Over the next 25 years, however, the “information revolution,” in tandem with the contraction of the British welfare state, would herald major change, creating a less uniform, more flexible, and disorganized educational system which some would argue marks the beginnings of decline. Core LIS curricula laid down in the 1960s and 1970s have been superseded by a range of information-related courses, beginning in the late 1980s with “information studies” programs and subsequently shifting in the 1990s to “information management” curricula constructed around new management studies approaches to information resource management (IRM). More latterly, a good number of LIS schools have experimented (not totally successfully) with fashionable “niche” offerings such as Knowledge Management; Health Informatics; Web Information Management; and so on. Flexible modes of study such as distance and “blended” learning have also become popular: Aberystwyth University and Robert Gordon University, Aberdeen currently offering successful distance degree programs. (CILIP provides a list of currently accredited courses).^[52] An alternative mechanism for demonstrating professional competence (and route to CILIP membership) has also been created through the establishment of a state regulated National Vocational Qualification (NVQ) in Information and Library Work—a program which ironically echoes much of the apprenticeship culture dominant in U.K. librarianship before the “academic drift” of the

1960s. CILIP, and most of the U.K. LIS community, have welcomed these developments, pointing to the expansion of LIS into new fields such as knowledge management and its responsiveness to a flexible, postindustrial labor market. However, these changes have also been accompanied by institutional retrenchment in the schools and departments of LIS. Undergraduate degrees in librarianship and information science have declined in popularity—only 13 of these were offered in 2007 compared with 24 in 2000.^[53] Library schools themselves have been forced to cut back their staff numbers, and the majority, especially those in the new universities (former “polytechnics”), have lost their autonomy being absorbed into computing, information technology or business schools and faculties. Two universities, Queen’s University Belfast and Birmingham City University (formerly Birmingham Polytechnic), no longer offer accredited courses in LIS.

The permanent impact of these developments on the future of the LIS disciplines in the United Kingdom is still uncertain. On the positive side, however, it is clear over the last decade that, despite the retrenchments noted above, and despite the final demise of BLRDD in 1999, research in the LIS field has recovered and in some areas flourished. British Library Research and Development Department has been replaced by a multiplicity of research funders—the European Commission (which made 89 awards in 2003); the U.K. Joint Information Systems Committee (74); the Arts and Humanities Research Council (AHRC) (31); and the Museums Libraries and Archives Council (10) being the largest sources of support.^[54] This devolution of funding has undoubtedly resulted in a broadening of the scope of research compared with the BLRDD era: LIS research has more or less effectively expanded into fields such as information policy; European research; information resource management; and information and library history. Moreover, the interest of some new funders in supporting highly applied, developmental, “evidence-based” and contract-driven projects has cemented the involvement in the field of research consultancies such as Electronic Publishing Services Ltd; TFPL; TALIS; and Information Management Associates.

Despite this competition, most academic schools of LIS have managed to expand their research activities. Research “centers,” such as CERLIM at Manchester Metropolitan University and CIBER at City University (more recently UCL) have fostered research cultures and focused research interests, and the majority of LIS schools have increased their throughput of doctoral students. Librarianship and information science departments have also taken the lion’s share of “academic” research funding allocated to the discipline by the AHRC. Most important, however, has been the impact of the Higher Education Funding Council’s Research Assessment Exercise (RAE), a periodic review of research performance in U.K. universities which began in 1992 and was repeated in 1996, 2001, and 2007. (See Nicholas^[54] for the 2001 RAE tables and

ratings of schools and departments. The 2007 Research Assessment Exercise is still underway at the time of writing this entry, July 2008). Library and Information Management effectively established itself as a separate “unit of assessment” for these exercises, and this has enabled research intensive schools (such as those at Sheffield University, Loughborough University, and City University—all awarded a top 5 or 5* rating in 2001) together with groupings of successful LIS researchers elsewhere to showcase their activities in the eyes of their parent institutions, the wider academic community and the funding bodies. In this way, visibly successful research has, over the last 10 years, to some degree compensated for the problems faced by U.K. schools of LIS with issues such as curriculum offerings, student recruitment, and institutional restructuring. Whether or not LIS researchers and academics will be able to consolidate this position—and maintain library and information science as a distinct “discipline” in British universities in the twenty-first century—will depend not only on the quality of their research and teaching but, ultimately, upon the future resilience (and influence) of the U.K. library and information community itself.

United Kingdom: Museums and Museology

Sarah Elliott

Peter Davis

International Centre for Cultural and Heritage Studies, Newcastle University, Newcastle upon Tyne, U.K.

Abstract

This entry attempts to capture the rich diversity of museums in the United Kingdom. Following a discussion of the evolution of British museums in their historical context from the private collecting through the profound impact of global exploration the authors examine major changes in the museum sector in the latter part of the twentieth century. Because discussion on types of museum organized according to discipline is rendered problematic by the frequent occurrence of multidisciplinary in U.K. collections, this entry uses a framework of organization and funding to identify seven types of institutions: 1) national; 2) university; 3) armed services; 4) local authority; 5) independent; 6) English Heritage; 7) the National Trust; and 8) the living collections of zoos and botanical gardens.

INTRODUCTION

The museums scene in the United Kingdom has been described as “fascinatingly variegated” and “idiosyncratic,” a state of affairs resulting from a history of perpetual development linked to an engagement with shifting social needs but without a strategic framework.^[1] This entry attempts to capture this arguably unique diversity, first locating the museums of the United Kingdom in their historical context—from the private collecting for founding collections that enabled their establishment in the country, through the profound impact of global exploration, trade and empire, the significance of national societies and local literary and philosophical societies, and the effects of the Museums Act (1845) and other Acts of Parliament in the mid-1800s, to the major changes in the sector in the latter part of the twentieth century.

An overview of museum provision is then presented. Discussion on types of museum organized according to discipline is rendered problematic by the frequent occurrence of multidisciplinary in U.K. collections, thus they are articulated here according to frameworks of organization and funding—national, university, armed services, local authority, and independent—with additional classifications for English Heritage, the arguably statutorily anomalous National Trust, and the living collections of zoos and botanical gardens. The record reveals that the United Kingdom was in the vanguard of public museum provision, but as understanding of the factors that lead to *effective* provision has advanced, so the significance of the integrated museum profession, and the mix of skills, knowledge, and attitudes of those engaged in museum work, has become clear. An outline of the museum workforce and museum work follows, together with a brief

account of the professional associations, specialist groups and museum training courses that underpin them.

Currently, the museums of the United Kingdom are seen as a public service, redefined and moved beyond their traditional cultural role into coordinates for change in society. They have undergone a remarkable renaissance over recent years with important funding strands coming online, but the sector is still seen as fragile and a formal national structure, anchoring museums’ support within government, remains a cultural policy challenge.

A BRIEF HISTORY OF MUSEUMS IN THE UNITED KINGDOM

The history of U.K. museums has been exceptionally well-documented, with publications devoted to the histories of individual national museums,^[2] individual provincial museums,^[3] regional museum provision,^[4] and university collections.^[5] Early phases of collecting have been described by MacGregor^[6] and Hunter,^[7] amongst others. Academics have also addressed issues such as the history of museum architecture,^[8] collecting,^[9,10] and exhibitions.^[11,12] Although Alexander^[13] provides interesting insights on museum development in the United Kingdom, arguably the most comprehensive account has been provided by Lewis;^[14] much of the following is based on this.

Early private collections were formed in Britain in the early seventeenth century. Sir Robert Cotton (1571–1631), best known for his library, also collected coins, medals, and antiquities, and his friend Sir Walter Cope (d. 1614) traveled widely and amassed a variety of natural and cultural objects. John Tradescant I (1570–1638) knew Cope and had seen his museum, and it may be that the nature of

"Tradescant's Ark" at Lambeth, London was influenced by Cope's collection. Tradescant visited mainland Europe, Norway, and Algiers and used his contacts to develop his museum; when he died his son John II (1608–1662) took over the collection, adding to it during three visits to Virginia. In 1656, a catalog of the collection—*Museum Tradescantianum*—was published, "the first recorded use of the word 'museum' in England in its currently accepted form."^[15] The collection eventually passed to Elias Ashmole (1617–1692), who in turn gave it to Oxford University; the building which housed the collection in Oxford, with its associated laboratory and teaching facilities, eventually became known as the Ashmolean Museum.^[16]

Although the Tradescants are well known, there were rivals to the "Ark," including the museum belonging to Robert Hubert (Forges) near St. Paul's; Hubert was an entrepreneur, inviting the nobility and academics to see his collections, so giving them additional status. He created special exhibitions, held private views and could give guided tours in four languages. Other collectors from the same period include John Bargrave (1610–1680) and Sir James Balfour (1600–1657). Later in the century, collectors such as James Petiver (1663–1718) were beginning to take a different approach to their collections, publishing catalogs of them, and actively promoting scientific and rational collecting. Petiver's collections were acquired by Sir Hans Sloane (1660–1753), whose museum became the foundation of the British Museum.

The Enlightenment witnessed the creation of an international scientific network. Diderot (1713–1784) produced his *Encyclopedie* (1751–1777); people began to question the nature of fossils and geological time, Lamarck (1744–1829) and Erasmus Darwin (1731–1802) pondered the nature of evolution. There was a growing interest in other cultures and in world geography and from about 1750 there was new emphasis on aesthetics, sentiment, and common virtues which were expressed in poetry, fashion, and art. There was increasing access to information and free speech, and above all the use of reason to understand the world. These changes had a profound effect on collecting and the establishment of museums in Britain and elsewhere in Europe. At the forefront were national societies, especially the Royal Society (founded 1660), but local societies such as the Manchester Literary and Philosophical Society (1781), the Birmingham Lunar Society (1766), and the Philosophical Society of Edinburgh (1732), all developed major collections. The end result of this intellectual activity was the establishment of the first public museums—for example in Britain the Ashmolean Museum (1683), the Sedgwick Museum, Cambridge (1728), and the British Museum (1759). Meanwhile the private museums developed by Sir Ashton Lever (1774) and William Bullock (1795) were also extremely popular with the public, using novel methods of display such as habitat groups of animals.

The nineteenth century was a time of massive social change, a drift to urban living began, as did the generation of wealth which allowed some people a degree of leisure time. It was a time of educational reforms and the founding of learned organizations such as the Belfast Natural History Society (1821), Leeds Literary and Philosophical Society (1821), Manchester Natural History Society (1821), and the Newcastle upon Tyne Literary and Philosophical Society (1793). Brears and Davies^[4] have discussed the significance of the Literary and Philosophical Societies in the formation of provincial museums in Britain. Other bodies played a vital role in promoting local museum collections which were made accessible to the public—especially Naturalists' Field Clubs and Mechanics Institutes. The former encouraged active field work, the formation of local collections, and the dissemination of knowledge in local specialist journals.

Urbanization and industrialization created cities of great economic strength and power; they were frequently centers of trade with the rest of the world, at a time when Britain was developing its Empire and exploring all corners of the world. Cities such as Liverpool, Bristol, Glasgow, and Newcastle had access to new cultures, new environments. The combination of growing wealth, civic pride, and fashionable learned societies, aided by the Victorian ethic for self-improvement, led to collection-building on a grand scale. Many of Britain's great museum buildings were established at this time, including the British Museum (1823), the National Gallery (1838), the Fitzwilliam Museum, Cambridge (1816), and the Hunterian Museum, Glasgow (1807).

Many of the collections formed by the learned societies and private individuals were transferred to local governmental authorities following the passing of the Museums Act in 1845 which enabled local authorities to levy a 1/2 penny rate if the population exceeded 10,000. Lewis^[17] notes the museums were to be provided "for instruction and recreation." Sunderland Museum is notable as the first ever municipal museum (1846), its founding collections made by a late eighteenth-century scientific society; Canterbury (1847) and Warrington (1848) followed, again utilizing collections made by local learned societies. Other Acts of Parliament followed, including the Public Libraries and Museums Acts of 1850 and 1855; from this time Libraries were mandatory functions of local authorities, whereas museums remained a discretionary service. The Acts had an immediate effect; by 1860 there were some 90 museums in Britain; when the British Association reported on museums in 1887 this figure had grown to 217.^[18] This growth in the number of municipal museums led to a call for increasing professionalism; consequently the Museums Association was inaugurated at York in June 1889 to represent not only curators but also representatives from museum committees. The educational potential of museums began to be more widely recognized about this time, with Liverpool organizing loan collections for use in schools from 1884.

Lewis^[19] regards the period between the two World Wars as a time of “reassessment and consolidation,” and describes in detail the various reports aided by the Carnegie United Kingdom Trust, the Museums Association and the Standing Commission on Museums and Galleries. The Miers Report (1929) is regarded as particularly influential in changing conventional practices in museums, encouraging them to relate more closely to their local communities, promote educational activities, and provide better training for museum staff. The years following World War II, a period of severe financial restraint, saw little investment in museums; despite this a survey of provincial museums carried out in 1963 recorded some 876 sites with collections and open to the public. The period up until 1975 was one of even more rapid growth and diversity in the museum sector; site museums, community involvement, industrial museums, interpretive centers, and an emphasis on the conservation of natural and cultural areas flourished against a backdrop of the growing environmental movement. New museums were opened, including the Museum of London and branch museums of the Science Museum in York and Bradford; by 1987 the Museums Association estimated that the total number of museums in the United Kingdom had reached 2131.

The latter part of the twentieth century witnessed major changes in the museums sector in the United Kingdom. Concerns about minimum professional standards led to the Museum Association’s “Accreditation” guidelines, and then to the Museum and Galleries Commission’s “Registration” scheme. Museums entered the digital age, with the initial emphasis being on the ways new technologies could assist with collections documentation; support and the setting of documentation standards was aided by the Museums Documentation Association from 1977. Arguably the main impact on museums from the 1980s onwards was reduced levels of government funding; in order to deal with financial strictures museums had either to cut costs—usually through voluntary and forced redundancies or reductions in activities—or seek new ways of raising money. Museums increasingly had to demonstrate they were using funds wisely; such accountability also meant a significant change in the staff structures of museums as specialist curatorial posts were reduced to make way for marketing and promotional staff or those delivering public oriented projects. There were major changes in management style in museums as they became more business oriented; strategic planning, marketing, corporate sponsorship, business development, and project planning became techniques employed by all museums. Priorities were re-assessed and financial targets considered against the growing demands on museums to not only conserve the nation’s heritage but also to play a major social role, contributing to education, the economy, and quality of life. These multiple pressures on museums have continued to grow in the twenty-first century and are discussed further below.

MUSEUM PROVISION IN THE UNITED KINGDOM: MUSEUM TYPES

The distinctiveness of museums in the United Kingdom can be observed in terms of their disciplinarity and frequently their multidisciplinarity, but also in the ways they are organized and funded.^[20] Although there is merit in describing the U.K. museum scene by focusing on the museums’ *raison d’être*—their collections, their arguably unparalleled diversity makes such classification problematic. The scene, comprising some 2500 museums,^[21] can be more usefully articulated through an engagement with governance. Through this, they can be categorized into five main groupings, namely national, university, armed services, local authority, and independent, with an additional classification for those museums owned and managed by the National Trust and by English Heritage. The Museums and Galleries Commission’s DOMUS database categorized museums in this way.^[22] Differentiated by exhibiting living objects (examples of natural history)^[23] but sharing many common features in performing scientific, educational and recreational roles, zoos, botanical gardens, and aquaria are *forms* of museum^[24] and are included here.

National Museums

In the United Kingdom, there is no statutory definition of National Museums, their authority residing in miscellaneous acts, charters, and Treasury minutes.^[25] However, those institutions recognized as such can be defined in practice by their direct or core government funding, their administration by Boards of Trustees on the nation’s behalf, and the national significance of their collections.^[26] The Museums, Libraries and Archives Council’s *List of Museums with Full Registration or Accreditation: July 2008* records a total of 53 individual museums within its National Museums section.

The National Museums are based in London, Liverpool, Edinburgh, Cardiff, and Belfast, and most have branches in other cities or operate from several sites. The British Museum in London, established by an Act of Parliament in 1753 around a collection bequeathed by the physician, naturalist, and collector Sir Hans Sloane, is the oldest and largest. Other prominent London Nationals include the Victoria and Albert Museum (art and design), the Natural History Museum, and the Science Museum, all arrayed on a tract of land established in South Kensington as a cultural and educational district after the Great Exhibition of 1851. The National Gallery, housing one of the world’s greatest collections of Western European paintings, and the Tate, a family of four galleries (two in London) holding British Art from 1500 and international modern art, complete the “big six” of the 13 based in the capital. On Merseyside, National Museums Liverpool is a

varied grouping of eight museums made public following the abolition of Merseyside County Council in 1986. Amgueddfa Cymru/National Museum Wales is a network of seven museums, with the National Museum Cardiff, opened to the public in 1927, at its heart. In Scotland, the National Galleries of Scotland has branches in Edinburgh, while National Museums Scotland operates sites both within the capital and further south near Dumfries (National Museum of Costume) and in East Kilbride (Museum of Rural Life). More recently, the National Museums and Galleries of Northern Ireland was established under the Museums and Galleries (Northern Ireland) Order of 1998.

Between them, the National Museums receive approximately 35 million visits a year (figures for 2005/6 from a National Museums Directors' Conference brief after Department for Culture Media and Sport data, see the National Museums Directors' Conference),^[27] and in 2005–2006 were allocated some £300 million in grants-in-aid with just over £22 million capital grants-in-aid from central government.^[28] Income is also generated by the National Lottery, donations and sponsorship, and trading. The overall economic impact of the National Museums is hugely significant, at approximately £1.5 billion per annum.^[29]

University Museums

The genealogy of museums in the United Kingdom is intimately linked to its universities.^[30] The oldest public museum in the country, and arguably the world, is the Ashmolean Museum of the University of Oxford. Its founding collections, based on the miscellaneous curiosities of the Tradescant Ark (see history section above), emerged in the public domain within a purpose-built museum in 1683. Other donations to higher education institutions were recorded much earlier, but the subsequent development of systematic collections in scientific disciplines facilitated the emergence of several great teaching and research museums.^[30] Cambridge University, for example, developed a substantial new museum of geology, zoology, and archaeology. The Sedgwick Museum was founded by the bequest of Dr John Woodward (1665–1728) on his death in 1728. In 1842 Woodward's collection (then the "Woodwardian Museum," comprising four cabinets of minerals, rocks and fossils), was moved to the new Cockerell building, its first permanent home. After the extensive collecting of Professor Adam Sedgwick (1785–1873), the Museum moved again in 1904 to the present Sedgwick Museum building (for more on the founding collection, see Price).^[31] Elsewhere, Glasgow University was bequeathed the anatomical collection of John Hunter and opened the Hunterian Museum (1807), while Owens College (later Manchester University) took over the long-established collections of the local Natural History Society to create

the Manchester Museum (1888). Numerous other smaller departmental collections also emerged.

The importance of the major university museums is signaled today by the Department for Culture, Media, and Sport (DCMS) identification of their collections as being of national or international significance ("Designation"); there are currently around 400 higher education museums, galleries and collections, together comprising 4% of the United Kingdom's museum sector,^[32] but they are keepers of 30% of all Designated collections in the country.^[32] Along with the Ashmolean, the Sedgwick, and the Manchester Museums, other holders of Designated collections include the Fitzwilliam Museum (Cambridge University) together with the more constrained but comparable institutions of the Whitworth Art Gallery (Manchester University), the Courtauld Institute Gallery (University of London), the Barber Institute of Fine Arts and the Lapworth Museum (Birmingham University), and the Pitt Rivers Museum and the Museum of Natural History at Oxford University. These great institutions are among the hundred or so higher education museums open on a regular basis, and among the 38 that receive core funding from the Arts and Humanities Research Council (AHRC) in England and the Scottish Higher Education Funding Council (SHEFC).^[32] The AHRC/SHEFC-funded museums deliver beyond their traditional commitment to academic audiences, maintaining a range of public services, education, and exhibition programs comparable to those of regional and national museums. Attracting some 2 million visitors a year (2002 figures), they have a good track record of wider social engagement, and thus are increasingly important in advancing the cultural contribution of their parent institutions. The vast majority of higher education museums, galleries and collections, however, are little known. Buried within their departments and institutions, they "are solely dependent on the very modest resources available to them from higher education teaching and research budgets, generally under the auspices of their academic department."^[30] According to a recent report, many have deteriorating physical infrastructure, and are suffering from decreasing revenue funding and a consequent erosion of their intellectual and heritage capital.^[33]

Armed Services Museums

A third category of museums that are mainly or partly funded by central government is that of the approximately 200 museums of the armed services.^[34] The long and rich tradition of the British armed forces (the Royal Navy has been extant for 450 years, the British Army's history spans over three centuries, and the Royal Air Force has been in operation since 1918), and particularly the stable units of the army with set depots in which historical artefacts could accumulate and the strong county connection of the regiments, account for this unusually high number of

museums dealing with some aspect of military history or containing military collections.^[35] Of these military museums, four Nationals have a direct armed services remit: the National Army Museum, the Royal Air Force Museum, the Imperial War Museum, and the National War Museum of Scotland (part of National Museums Scotland).

The National Army Museum, established by Royal Charter in 1960 and now sited in Chelsea, is a repository of the history and heritage of the Regular and Auxiliary forces of the British Army and of the Commonwealth. Through its collections of uniforms, weapons, medals, paintings, drawings, archives, and transport, a narrative from Agincourt in the early fifteenth century to peace-keeping in the twenty-first is presented. The Museum also has a role “supporting the Defence Purpose through its contribution to the Army’s image in society; to the remembrance of those who have served, and to the education of Servicemen and Servicewomen,”^[36] and is committed to broader societal learning output. The Royal Air Force Museum was founded 3 years later, with collections held in Hendon (London) and at its outstation in Cosford, Shropshire comprising materials recording the history of the Royal Air Force and its relationship with aviation generally. It was World War I, however, that stimulated the formation of an all-service national museum dedicated to all aspects of armed conflicts involving Britain and the Commonwealth since 1914. The Imperial War Museum’s original intent to comprehensively record and commemorate the Great War effected an encyclopedic coverage of that conflict, but its terms of reference were soon extended, initially to World War II and then to British military actions up to the present day. In Scotland, the National War Museum (formerly the Scottish United Services Museum) sited in Edinburgh Castle also has the combined services in its mandate (albeit within the Scottish context) and was created in 1930 to commemorate the sacrifice made by Scotland in World War I.^[37] Portrayal of the Royal Navy is not undertaken by a single museum, “its essential story being told by the National Maritime Museum and the four designated but non-national museums: The Royal Navy Museum Portsmouth, The Royal Marines Museum in Southsea, The Royal Navy Submarine Museum in Gosport, [and] The Fleet Air Arm Museum in Yeovilton.”^[38]

Other Nationals, namely the Royal Armouries (1680s) and the Science Museum (1857), have collections related to the history of defence, but “the depiction of war through museums exhibitions (in the United Kingdom) is most likely to be found in regimental museums”^[39] and those allied to the corps of the British Army. Over 130 exist,^[40] including strong regimental museum provision in Scotland and Wales, and five in Northern Ireland. (Those in Northern Ireland are: Royal Irish Fusiliers Regimental Museum, Armagh; Royal Ulster Rifles Museum, Belfast; North Irish Horse Regimental Collection [temporarily closed to the

public], Belfast; Royal Irish Regiment Museum, Ballymena [closed pending relocation]; Royal Inniskilling Fusiliers Regimental Museum, Enniskillen, see Army Museums).^[41] Formed not to present war per se, but “for the specific purpose of instilling and fostering in the regiment the *esprit de corps* which enables it to fight more effectively,”^[39] regimental museums have strong territorial links—regionalism and the military being a binary notion forged by King George III, “who first realized the importance of fostering regional loyalties and attitudes for soldiers serving together.”^[42] Despite the amalgamations of many regiments in the 1960s, longstanding local links have enabled many collections to be assimilated into local authority museums. Indeed, the Museums and Galleries Commission report of 1990 on armed services museums noted that nearly 40 were managed within local authority museums.^[43] Notable regimental and corps museums include those among the first to be formed (often museums of technology as well as military)—the Royal Artillery Regiment Museums in Woolwich (1778) and the Royal Engineers Museum in Chatham (1875) have collections based on the models and exhibits used at their training establishments—and the Tank Museum at Bovington.

Almost all regimental and corps museums are instituted as charitable trusts, most receive support from the Ministry of Defence (MOD) (grant-in-aid funding of about £4.8 million to the National Army Museum, and £4–5 million to 69 others, see Stephens)^[44] and just under half still occupy MOD property.^[45] Their development today is also aided to a considerable degree by the Army Museums Ogilby Trust, a charity set up in 1954 to assist the museums with funds, advocacy, information, and advice.

Local Authority Museums

Prior to any direct reference to local authority museums, some explication is pertinent of the rather arcane local government environment within which they operate. Indeed, a greatly-increased complexity has characterized this environment over the last decade, with devolved governments in Edinburgh, Cardiff, and Belfast adding a further layer of complication.^[46] Babbidge^[47] provides a good overview of the local authority sector in Britain and its interface with museums, but its structure can be briefly drawn here. The architecture of local government in the United Kingdom is, as noted, complex, its history one of gradual evolution and change since the Middle Ages. The historic counties, established in England for Norman administration and based on earlier Anglo-Saxon kingdoms and shires, however, acted as agencies of the state for several hundred years and continue to form (albeit with altered boundaries) the basis of modern local government. In Wales, Henry VIII (r.1509–1547) imposed an administrative structure on that country with the Act of Union (1536), and the names and boundaries remained virtually the same until reorganization in 1974. In Scotland, the

royal free burghs (a “burgh” is a Scots term for a town or municipality) were highly autonomous units of local government from the twelfth century, developing provision of basic services for local people until their abolition in 1975; current arrangements for Scotland and Wales, however, date from the mid-1990s with the creation of 32 all-purpose unitary councils in the former and 22 in the latter. The 1970s also ushered change in Northern Ireland, when the present pattern of local government with 26 councils was established. The single tier all-purpose council, also found in parts of England and including the City of London, 32 London Boroughs, 36 Metropolitan and 47 Shire Unitary, is responsible for all local authority functions. In 2000 a new Greater London Authority was created (directly-elected Mayor and separately elected Assembly) with responsibility for four functional bodies—the Metropolitan Police Authority, the London Fire and Emergency Planning Authority, Transport for London and the London Development Agency. The London Borough Councils, however, essentially perform the same functions as any single tier authority. The remainder of England has a two tier system, in which two separate councils divide responsibilities—county councils (the upper tier) are mandated core functions and district councils (the lower tier) deliver more local services. Across Britain, the bottom tier of local government comprises Town, Parish, and Community Councils.

Most councils (around 75% of the 442 first and second tier local authorities in Britain) operate some form of museum service (Babbidge describes how the councils use one, or a mix of some, or all, of the following means of provision: “193 (44%) make direct museum provision; around 25 have devolved management of their museum services to a specially-created charity; approximately 50 participate in joint arrangements with other local authorities; one-third core-fund independent museums, whether in their localities, or occasionally, outside their administrative areas”),^[48] although the museums under their (direct or indirect) authority vary considerably in size, quality, and importance. Many of the major regional museums were founded in the nineteenth century with encyclopedic collections (see history section above) and are housed in elegant civic buildings. Examples include museums and galleries at Birmingham and Bristol. Birmingham Museum and Art Gallery, opened in purpose-built accommodation by the Prince of Wales (later King Edward VII) in 1885, originally represented the desire of prominent citizens to improve manufacturing quality in the “City of a Thousand Trades” as well as to better the lot of the working man through exposure to art and natural history.^[49] It drew on contributions and donations from the Birmingham glass manufacturer Thomas Clarkson Osler, the great industrialist Richard Tangye, the glass-worker Thomas Collier Barnes, and the proprietor of the Birmingham Daily Post, John Feeny. Today, the institution’s collections cover fine and applied arts, archeology

and ethnography, natural history and social history. In Bristol, the City Museum and Art Gallery’s origins lie in the foundation of the Bristol Institution for the Advancement of Science and Art (1823) and the slightly older Bristol Literary and Philosophical Society, and it benefited from the donations of the tobacco baron Sir William Henry Wills (1830–1911). In Scotland, the first municipal authority to consider museum provision was Glasgow, and when the coachbuilder and art collector Archibald McLellan (1796–1854) bequeathed a collection of 400 paintings, the core of the city’s Old Master collection was laid down. Museum provision of other local authorities in Scotland around the time included Paisley (1870) and Dundee (1873), the latter founded on the collections of the Watt Institution.^[50]

Outwith the large conurbations a huge number of smaller, district authority museums perform an important and active role as “interpreters of local history, and as biological, geological and archaeological record centres,” all maintaining a commitment to local education and community service.^[51] The Central Museum at Southend on Sea, for example, covers geology, archeology, social and local history, local wildlife, and the industrial history of South East Essex.^[52] Smaller independent museums are also supported by many local authorities in whose areas they operate.

Local authorities form a significant museum provider in the United Kingdom, with the 22 largest local authority services attracting some 12 million visitors annually.^[53] Lawley^[53] notes that 40% of Registered museums in the United Kingdom are operated by local councils. Overall, however, regional provision is variable, a characteristic rooted in recent years in unreliable revenue funding, and historically in piecemeal development *sans* clear legislative frameworks.^[54] In England and Wales, the nature and extent of provision is articulated by the Public Libraries and Museums Act 1964, which gives county and district councils *discretionary* powers to “provide and maintain museums and art galleries within their administrative area or elsewhere in England and Wales and do all such things as are as necessary or expedient for or in connection with the provision and maintenance of those museums,” and in Scotland by the Local Government and Planning (Scotland) Act 1982 (as amended), which places upon local authorities a duty to “ensure that there is adequate provision of facilities for the inhabitants of their area for recreational, sporting, cultural, and social activities.”

A much stronger strategic and operational framework for museums and galleries in England was envisaged with the publication of the Resource report *Renaissance in the Regions* (2001). Produced by a task force convened at the behest of Chris Smith, then Secretary of State for Culture, Media, and Sport, to review the state of the nation’s network of regional museums, the report identified problems including inconsistent provision, sectoral fragmentation, and a failure to sustainably deliver government policy

(e.g. education, creativity, and social inclusion), and recommended a major redefinition of museum structural interfaces and cooperative practice. It proposed a transformational initiative that sought to make museums fit for the twenty-first century. With the uptake of Renaissance, years of under-investment have been reversed, with nearly £150 million allocated to regional museums between 2002 and 2008, and a new structure—"a 'hub' for each of the nine regions made up of a group of the largest museums, funded by central government and working together to improve museums across the whole region"^[55]—put in place. The achievements of Renaissance, however, have not reduced the vulnerability of nonstatutory services. In 2005/2006, council spending on museums and galleries in Britain amounted to just over £320 million, or 0.19% of total local authority net expenditure,^[56] and cuts and closures in London^[57] and a funding crisis in Wales, where "there is nothing like the investment of Renaissance,"^[58] remain major concerns.

Independent Museums

A substantial number of museums in the United Kingdom are managed outside the traditional frameworks of central or local government. In the nomenclature of recent years they are known as "independent" museums. Defined by the Association of Independent Museums (AIM) as having "a board of trustees or other policy making body which are not directly controlled by or the direct responsibility of any central government department or local or regional authority or similar political subdivision," they comprise museums with charitable status (and therefore within the public sector) and those that operate for commercial gain.^[59] Some have considerable public authority financial support, and others receive little or none.^[60] In 2000, there were thought to be approximately 1215 such museums in the United Kingdom, with around half of a specialist nature.^[61]

Although the majority have been created since the mid-1960s in a flurry of growth, the first generation of independent museums in the United Kingdom is arguably those with roots in the activities of societies, clubs, or other groups of interested people. As Cossons^[60] points out,

many of the great collections now held by public authorities, and some of the buildings that house them, have their origins in the activities of... societies, and gentlemen's clubs, which if they were still being run in this way today, would certainly place them in the category of independent museums.

Despite local authority accession of numerous collections and buildings, some societies' museums, such as that of the Sussex Archaeological Society at Lewes (1846), still exist in their original forms, and others retain an

independent identity with a governing body replete with society members.^[60] Overall, however, the decline of society museums—run as originally established—was effected by monetary constraints. Holding to principles of free admission, they were sustained by membership subscription and endowments, a funding pattern that collapsed after the first generation of members disappeared. Rising operating and care costs compounded the issue and necessitated a linkage with local authorities.^[62] Cossons^[62] notes that four decades ago it would have been a rational assumption that "these early society museums formed part of the transitional, formative phase of museum development in this country, a phase that had been superseded by a more formalized Local Authority based structure of museums" delivering a service to people in their locality. In the 1970s, however, shifts in public attitudes toward the material traditionally held in museums, increased affluence, leisure and mobility, a new popular awareness and sensitivity toward the environment and place, and a keenly felt need to record the changing industrial landscape coalesced and catalyzed a new breed of museum.

The independent museums that emerged swept away the "dull and dusty" image projected by local authority museums^[63] at the time and could be characterized by "a pioneering spirit, a can-do attitude and an innovative, entrepreneurial approach."^[64] Established by community or industry groups and covering areas previously generally unrepresented in the traditional museums milieu—industrial archeology, transport history, vernacular architecture, and building preservation (often *in situ*)—they operated as charitable trusts and raised their revenue from admission fees and commercial activities. As well as the world renowned Ironbridge, now a collection of 10 museums, they included the Weald and Downland Open Air Museum in West Sussex, the National Motor Museum at Beaulieu in Hampshire, the Bass Museum in Burton upon Trent (latterly the Coors Visitor Centre), and the Gladstone Working Pottery Museum in Stoke-on-Trent.^[63] Ironbridge and the Gladstone Working Pottery Museum typify the important strain of new museums created as a direct result of the changes in the industrial landscape, where the unattractive relics of past industrial activity—evidence of an important cultural phenomenon of world significance—were being rapidly eliminated. The former was established in 1967 to preserve and interpret the remains of the Industrial Revolution around the gorge spanned by world's first cast iron bridge at Coalbrookdale. The latter, centered on bottle ovens typical of hundreds that dominated the Stoke skyline in the nineteenth and early twentieth centuries, opened in 1974 as a result of an eleventh hour reprieve from demolition after local people mobilized to save the site. Other smaller independent museums have been initiated by local communities and embrace all subjects within a locality, tapping into a local scale desire to see evidence of communities' own history collected, and preserved in their own local museum.^[65]

The independent museum constituency continued to grow in the decades following the 1970s, and its total income is now approximately £300 million, a quarter of the total museums economy.^[59] Their influence on the wider museum world in the United Kingdom has been strong, especially their entrepreneurship and commercial attitude; running shops, events, cafes, and visitor attractions have been widely adopted as mainstream museums accept the notion of social entrepreneurship.^[63] Many of the display and interpretation techniques employed by independent museums have also been embraced by the public sector.^[66] More recently, it is “The Trust model popularized by independents [that] is now heading for the mainstream as a growing number of local authorities explore the advantages of converting their museum services to (semi) independent charities.”^[67] The management of Glasgow’s museums and galleries, for example, has been entrusted to a charitable company—the Culture and Sport Glasgow Trust—in a move to facilitate greater financial flexibility and tap into Lottery and other funds. While other museum services, such as Sheffield and York, are also now run by charitable trusts, in Glasgow the new company will be responsible for the city’s entire cultural division.^[68]

NATIONAL TRUST AND ENGLISH HERITAGE

National Trust

Although for many years the National Trust ethos held that it did *not* operate museums,^[69] it is now widely recognized that the organization’s “entire ensemble of objects, buildings, gardens, landscapes and the cultural networks they are part of constitute a very live and relevant museum holding.”^[70] This museum holding is considerable. In 2006, the Trust became the largest accredited museum authority in the United Kingdom, with 149 properties registered as museums, or almost 10% of the national constituency of registered museums.^[71] Its land holdings comprise over 600,000 acres and 700 miles of coastline in a broad geographical spread over England, Wales, and Northern Ireland (Many National Trust properties house important collections of furniture, fine and decorative art, costumes, and antiquities. In the mid-1990s, the Museums and Galleries Registration Scheme was extended to include such collections. The National Trust’s land holdings, however, cannot be registered as museums, see Resource).^[72] The Trust is a charity completely independent of government, managed since 2005 by a Council and Board of Trustees, and relies on income through the fees of its 3.5 million subscribing members, donations and legacies, and revenue raised from commercial operations.^[73] Over 12 million visitors are attracted annually to the Trust’s charging properties, while over 50 million visit its open air holdings (Figures given

are for 2007, see National Trust).^[74] In Scotland, the National Trust for Scotland—founded in 1931 at the initiative of Rural Scotland—has similar statutory powers as the National Trust, but operates with an entirely independent constitution. Around 188,000 acres of countryside are in its care together with 128 properties, holdings that are supported by a membership of almost 300,000 and attract some 1.25 million visitors annually.^[75]

The National Trust was founded as a result of the vision and mobilizing activities of three Victorian philanthropists—Octavia Hill (1838–1912), a social reformer active in improving housing for the urban poor, Sir Robert Hunter (1844–1913), a solicitor involved with the Commons Preservation Society (founded in 1865 by John Ruskin, John Stuart Mill, William Morris and others to help protect the remaining communally held lands against enclosure), and Canon Hardwicke Rawnsley (1851–1920), a Lake District clergyman and poet—who recognized the need for an organization to act as a guardian of the nation’s natural and cultural heritage at a time of increasing threat from uncontrolled development and industrialization. The catalyst that led to the idea was the threat to a garden in Deptford, east London. The garden was Sayes Court, created by the seventeenth century diarist John Evelyn, whose “original plan of 1653 shows what must have been one of the finest gardens of the time.”^[76] In 1884 an Evelyn family scion approached Octavia Hill with a view to its safeguarding for the enjoyment of the public, but no organization was extant that had the legal power to hold property for preservation in perpetuity. She decided to engage with the ideas laid out in a paper sent to the National Association for the Promotion of Social Science by Robert Hunter in which he posited the notion of a “land company,” formed “with a view to the protection of public interests in the open spaces of the country.”^[77] The idea had come too late to secure Sayes Court,^[78] but some ten years later, in January 1895, the “National Trust” was formally constituted as a public, nonprofit organization, vested with the power to:

promote the permanent preservation for the benefit of the nation of lands and tenements, including buildings, of beauty or historic interest, and as regards lands for the preservation, so far as practicable, of their natural aspect, features and animal and plant life (National Trust Act 1907).

The first building acquired by the Trust was the fourteenth century half-timbered Clergy House at Alfriston, Sussex, in 1896, but soon Barras Head, overlooking the rocky outcrop associated with King Arthur on the Cornish coast, the sixteenth century Joiners’ Hall in Salisbury and a small part of Wicken Fen near Cambridge (the Trust’s first nature reserve) were acquired, and the small but dedicated membership went on to amass more scenic lands and grand historic buildings. By 1900, Trust membership

stood at approximately 250 members and 180 properties, including the Farne Islands, large stretches of the Lake District, Bodium and Tattershall castles, Chedworth Roman villa and the Elizabethan manor house Barrington Court, came under Trust ownership.^[79] The year Barrington Court was purchased, the National Trust Act (1907) reached the Statute Book, conferring on the Trust the power to declare property inalienable. Today, the majority of Trust properties are protected in this way, securing their future in perpetuity.

English Heritage

English Heritage (officially the Historic Buildings and Monuments Commission for England) is a national agency with a broad remit of managing the historic environment in England. As an executive nondepartmental public body sponsored by the DCMS, it is the government's statutory adviser and works in partnership with central government departments, voluntary organizations and the private sector to "conserve and enhance the historic environment, broaden public access to the heritage (and) increase people's understanding of the past."^[80] These responsibilities are articulated in the National Heritage Act (1983) and are met by the organization in multiple ways, including championing the heritage nationally and internationally, conservation grant-giving, provision of preservation advice, and registering, protecting, and promoting significant historic buildings, monuments, and landscapes.^[80] English Heritage also maintains a public archive, the National Monuments Record, but is arguably most widely known for its care of Stonehenge and over 400 other historic properties on behalf of the nation. Although English Heritage receives grant-in-aid from the government (£129.4 million in 2007/2008), these historic properties generate valuable revenue (£11.4 million in admissions and a further £9.9 million from retail and catering in 2007/2008) through visitor numbers exceeding 5 million.^[81] They also provide the milieu for a membership of some 665,000.^[81] Similar bodies operate in Wales (Cadw), Scotland (Historic Scotland), and in Northern Ireland (the Environment and Heritage Service Northern Ireland).

ZOOS AND BOTANICAL GARDENS

Zoos

The pursuit of looking at wild animals has always been popular in Britain,^[82] with the first exotic specimen—a walrus—purportedly being exhibited in England during the reign of Alfred the Great (r. 871–899).^[82] There are accounts of the Norse explorer Othere, whose voyages in the northern seas was incorporated by King Alfred into an Anglo-Saxon translation of Orosius' universal history,

presenting the king with walrus tusks. Indeed, King Alfred's reign saw an influx of walrus ivory into England.^[83] Collections of exotic animals were exhibited in traveling fairs from Elizabethan times into the twentieth century, their acquisition facilitated by the great discoveries of the fifteenth and sixteenth centuries and access to a global mercantile shipping trade, but the first permanent zoological collection—comprising lions, lynx, leopards, camels, porcupines, and an owl^[82]—in the country was the result of a diplomatic gesture in the form of a ceremonial gift from William of Montpellier to King Henry I (r. 1100–1135). Another gift, this time of three leopards from the Holy Roman Emperor Frederick II to King Henry III (r. 1216–1272), led to the establishment of a menagerie in the Tower of London,^[82] some animals of which (including an elephant) could be viewed by the public.^[84]

From the late Middle Ages, the practice of keeping wild animals was still the province of the nobility and wealthy, and nonsystematically organized private collections in castles and estates across Britain proliferated, both conferring power and status on their owners and gratifying curiosity. At the beginning of the nineteenth century, however, serendipity (although still rife in determining the composition of many menageries of the era including the popular, arcade-like Exeter Exchange on London's Strand) was abandoned when the first zoological collection to be specifically founded for scientific purposes was established, that of the Zoological Society of London.

In a climate of colonial expansion, imperialism, and nationalism, Sir Stamford Raffles, a former colonial administrator in the East Indies, began the Zoological Society of London in 1826, its stated rationale being "the advancement of Zoology and Animal Physiology and the introduction of new and curious subjects of the Animal Kingdom"; The conferring of power enabled by the practice of keeping wild animals had now shifted to the nation, as "the rhetorical goal implicitly shared by Raffles and the other founders of the Zoological Society (was) to acquire, maintain and display representatives of the animal kingdom in a way that echoed and emphasized British pre-eminence."^[85] Two years later, the London Zoological Gardens opened in Regent's Park to fellows of the society and in 1846, to the public. The emphasis of policy and investigations carried out in the zoo at the time was shaped by landowners within the society, who promulgated domestication and acclimatization (a breeding farm was established at Kingston Hill to this end), and the naturalists, who "wished the zoo to stock exotic animals of taxonomic interest, without regard for their attractiveness, edibility, or other usefulness,"^[86] and focus on comparative anatomy and pathology. Today, the opportunities for scientific research are much broader, and the remit of the Zoological Society's research division (the Institute of Zoology, now in a strategic partnership with Cambridge University) spans evolutionary biology, genetics, ecology, reproductive biology, and wildlife epidemiology.^[87]

London Zoo, then *primus inter pare*, continues to be one of the world's greatest with excellent research and a mission that privileges the conservation of wild animals and their natural habitats.

The conservation message at London Zoo is explicit and reflects a sea-change in U.K. zoos in recent years as they have reconsidered their roles, often in light of “dwindling attendances and budget shortfalls.”^[88] Change has also been forced by the environmental lobby (as concern escalates for the preservation of wild stocks of animals), and shaped by the debate (triggered in the United Kingdom by the critical financial problems of London Zoo in the early 1990s) on the ethics of keeping wild animals and the need for “clarity about captivity (that is) essential to the humane transformation of zoos.”^[89] Furthermore, U. K. zoos are now regulated through the Zoo Licensing Act 1981 (as amended) under which they must meet minimum standards in *inter alia* animal husbandry and are obliged to participate in conservation and to promote public education and awareness of biodiversity conservation.^[90] Today, Holtorf^[91] notes, “Zoos are the most frequently visited types of museum in the world.” Despite an overall decrease in U.K. zoo attendance in the 40 years prior to 1998,^[92] shifts in zoo dynamics heavily promoting conservation as a key objective and the transformation of zoo environments (with commensurate enhancement of their credibility among the public) have arguably resulted in a gradual increase in zoo visits over the last 20 years in the kingdom.^[92,93] Indeed, Mackay^[94] has indicated that zoos generate some 7 million visits a year. This popularity has been crucial as many U.K. zoos operate under charitable status and “Visitors and their gate receipts, on-site expenditure and animal sponsorship are the lifeline for zoos, representing the major funding source for the majority of zoos in the United Kingdom.”^[95]

A large number of establishments display wild animals to the public in the United Kingdom—*The International Zoo Yearbook*^[96] lists 65 zoos and aquariums “together with a number of institutions with important animal collections, such as primate research centers, universities, and bird parks,” while the Department for the Environment, Food, and Rural Affairs’ list of licensed zoos operating in England alone in 2007 was much larger at 270 establishments.^[97] The Born Free Foundation’s 2000–2004 survey listed approximately 479 establishments displaying wild animals to the public for seven or more days a year in Britain.^[98] The Foundation’s latest estimate for the United Kingdom is over 530.^[99] London Zoo aside, at the developmental and attendance vanguard, some are particularly notable. Chester Zoo, generally acknowledged as the largest conventional U.K. zoo at 110 acres,^[100] was founded in the early 1930s by George Mottershead with a collection of animals from an earlier zoo at Shavington, near Crewe. Mottershead’s original desire to have a “zoo without bars” perhaps explains the zoo’s international renown today for innovative enclosure

designs. It is also known for its breeding successes and involvement in cooperative breeding programs, and plays an important role in developing conservation outreach, research, education, and marketing strategies. In 2007 visitor attendance was approximately 1.3 million, making the zoo the United Kingdom’s leading wildlife attraction and fourth in the kingdom’s most visited overall attractions.^[101] Edinburgh Zoo is also a highly successful visitor attraction (the second most visited charging attraction in Scotland), with 650,000 visitors recorded in 2006.^[96] The Royal Zoological Society of Scotland, founded in 1909, opened the zoo in 1913 and today it occupies 82 acres of parkland and is a leading center of conservation, education, and research.^[102] Recognizing the educational potential of defragmenting the exhibits and making reference to the “vital and multitudinous interfaces between plants and animals,”^[103] the zoo has adopted a holistic approach to habitat creation and plans to redevelop the entire site around four complex biotic communities, or biomes. (The four biomes are: Oceans and Wetlands, Tropical Forests, Woodlands, and Grasslands. The society is also creating two biomes at the Highland Wildlife Park, with Mountain and Tundra species.)^[104] Zoogeographic display is also a feature of Paignton Zoo in Devon after its £6 million transformation into an environmental park in 1996.^[105]

Botanical Gardens

At the turn of the new millennium a project described as “a showcase for economic botany and ethnobotany” constructed in the moon-like space of an exhausted china clay quarry in Cornwall attracted some 2 million visitors in its first full operating year, and through visitor spending brought £155 million into the economy of the county.^[106] The Eden Project, although differing from a traditional botanic garden in that its primary purpose is to draw a broad public contingent, interest them in plants and demonstrate human dependence on plants,^[107] is a hugely popular recent addition to the long and distinguished history of the maintenance of plant collections for scientific study and educational purposes in the United Kingdom.

Although the garden of John Gerrard in Holborn (1575) had botanical aspects and the formal gardens attributed to Dr. William Turner at the Duke of Somerset’s Syon House are linked to the naturalist’s *Names of Herbes* (1548),^[108] the earliest botanic garden in Britain was established with the benefaction of Sir Henry Danvers, first Earl of Danby, in 1621 by the University of Oxford as a physic garden, growing plants for medicinal research. Its “Nursery of Simples,” and plants in a conservatory “heated by a four-wheel fire basket of burning charcoal hauled back and forth by a gardener,” allowed students to learn their *materia medica* at a time when “the development of other sciences was being hampered by medieval tradition.”^[109] Contemporaneous with Oxford was the private garden (c. 1630) of John Tradescant (1570–1668) in South

Lambeth, (although Allen^[110] notes that he was more concerned with flowers that exhibited size, color, and strangeness, and fruits of succulence, than with the value of simples), and in 1673 the Chelsea Physic Garden was formed by the Society of Apothecaries. Scotland's first physic garden dates back to 1670 when a small plot of land at St. Anne's Yards adjacent to Holyrood Palace in Edinburgh was laid out by Dr. Robert Sibbald (later first Professor of Medicine at Edinburgh University) and Dr. Andrew Balfour.^[111] Although relocated in 1763 to a "green field" site on the ancient high road to Leith,^[111] the garden now known as the Royal Botanic Garden Edinburgh has unbroken lineage, an aspect shared with the Chelsea and Oxford gardens.

British botanic gardens morphed in the seventeenth and eighteenth centuries into colonial tropes of expansion and commercial development (Calcutta, Pamplemousse in Mauritius), and in the nineteenth century into civic gardens, established by "enlightened local government authorities (Sheffield, Glasgow)...as havens of green space in industrial cities"^[112] and advancing the horticultural aspects of their living collections. Today, the notion of a botanical garden as a sanctuary has emerged,^[113] responding (like zoos) to the demands of the conservation movement and taking "much of the responsibility for the genetic protection of threatened species, along with *ex situ* protection of plants with economic and ecological importance."^[113] Although Davis^[114] has argued that the influence of environmentalism on botanical gardens in the United Kingdom has been less evident than in other countries—especially the United States of America—there are some notable exceptions. The Royal Botanic Gardens Kew, is an iconic example.

The Royal Botanic Gardens, Kew is broadly recognized as one of the foremost centers for counsel, assistance, and action on plant and fungus conservation in the world, increasingly contributing to the development of international conservation strategies. Its programs engage with myriad endangered and threatened plants and their ecologically connected plant communities, and employ an advanced array of techniques (storage and cryopreservation of seeds, embryos and pollen, and micropropagation) to support *ex situ* and *in situ* conservation projects.^[115] The eminence and global influence of Kew, inscribed on the list of World Heritage Sites in 2003, has been constructed over centuries. From 1752, when Princess Augusta assisted by the keen botanist the third Earl of Bute and the architect Sir William Chambers began to develop her ten acres at Kew House, the Royal Botanic Gardens has functioned as a *ferme ornée* (an "ornamental farm" — a country estate laid out for profit [through gardening] and pleasure [by using aesthetic principles]) for King George III; the hub of botanical collecting and exchange (where economic botany had a direct practical relevance to both Britain and her colonies) under the "superintendence" of the king's chief botanic advisor Sir

Joseph Banks and similarly later under Dr. Joseph Dalton Hooker; a nursery for botanists and gardeners; and currently, in an age of ecological crisis, as a global leader in ecological stewardship.

Kew is a major visitor attraction. In 2007/2008, Kew and its sister garden at Wakehurst Place, West Sussex achieved just over 1.9 million visits.^[116] It is an executive nondepartmental public body (created by the National Heritage Act 1983) governed by a Board of Trustees and sponsored by the Department for the Environment, Food, and Rural Affairs, receiving £25.2 million grants-in-aid, with additional visitor income, investment income and fundraising totalling £30.8 million.^[116]

MUSEOLOGY AND FUTURE TRENDS

The Museum Profession

The (numerical) growth of the museum workforce in the United Kingdom has been considerable over the last 50 years, reflecting a major expansion in museum numbers (almost three new museums a week were opening in the 1980s) and the wider role of museums' approved missions within their communities and regions.^[117] The Digest of Museum Statistics analysis of 1999^[118] provides an indication of museum employment numbers across the then 1300 registered museums in the United Kingdom: 15,365 FTE (full-time equivalent) paid staff, of which 12,590 were in "permanent" positions, 2275 held temporary contracts, and 744 were employed as freelance specialists. However, the paid staff were considerably outnumbered by a volunteer workforce of approximately 25,206 FTE individuals. The survey revealed the national museums (6065), local authority museums (4799) and independent museums (3307) to be employers of the majority of paid staff, while the latter's utilization of some 15,786 volunteers placed it substantially ahead in unpaid staff numbers. In recent years, shifts in the U.K. labor market toward greater flexibility have been reflected in museums as "far higher levels of consultant and temporary or short-term contract staffing" have become evident.^[119] While the gender diversity of the museum workforce is generally good (51% of all curatorial and managerial positions in local authority sector and 46% for the nationals and independents)^[120]—indeed in some areas of museum practice (e.g. development) women dominate in numbers and seniority^[121]—there are still few women in the top museum posts.^[121] The ethnic diversity of the museum workforce, however, does not mirror the plurality of society (see issues section below).

Museum work has traditionally been associated with the curator, "an academic specializing in a specific collection-related field who can perform all the tasks necessary to the museums,"^[122] and in many parts of the world museums continue to function with a narrow range of staff

mainly consisting of “scholar-curators” at the professional level.^[123] In the United Kingdom, although the curator is still pivotal, Parr’s^[124] observation that museums “encompass a plurality of professions” is pertinent. The workforce comprises a variety of specialists in both subject and service fields, a result of the increasingly complex nature of museums and a more sophisticated understanding of all the factors that lead to effective provision. As Kavanagh^[122] notes:

In the larger museums teams of people work side by side: curators, education officers, conservators, exhibition technicians, designers, registrars, gallery assistants and attendants, outreach workers, audience advocates, writers, marketing specialists, security experts and managers. In smaller museums, curators, trained to have a high level of awareness and a good degree of competence in these skill areas, operate to the limits of their own versatility. They often work with freelance specialists.

The increasing prevalence of museum studies courses in the United Kingdom and frequent reference to a “museum profession” might suggest the homogenization of museum careers and a unitary profession,^[124] but the diversity in knowledge and skills noted above required *within* museums, and the diversity *among* museums in type, collections, and audience expectations, render this notion nugatory. As Kavanagh^[125] points out, “uniformity within the profession can be found more in a jointly held, but broad philosophy about the value of museums” and “an overarching sense of social and educational purpose” than in specific sets of skills and tasks. There is evidence of “a shared identity of museum professionalism,”^[125] and an understanding of professionalism not as an end in itself but as a “spiritual behaviour through which we seek to accomplish larger purposes.”^[126]

In Britain, momentum for the professionalization of museums and museum work began apace at the end of the nineteenth century, part of the growth in the new social phenomenon of professionalization that had seen many groups of workers—outwith the traditional learned professions of theology, medicine and law—seek status and recognition of their vocational endeavors through the constitution of distinct “professions.” This movement among museum workers, stressing the notion that the multiple museum types faced many of the same practical problems, effected the creation of the first museum association in the world (1889), and the earliest production of museological literature.^[127] Today, the Museums Association is the “single authoritative voice for the whole museum community,”^[128] disseminating information through *Museums Journal* (1901) and other print and Web-based output, lobbying government and setting ethical standards, engaging its members (5000 individual, 600 institutional and 250 corporate) in events around museum issues (including an annual conference) and furthering the position and qualification of museum staff.^[129]

Other professional associations operating at a national level include ICOM-UK, ICON (Institute of Conservation, the lead voice for the conservation of cultural heritage in the United Kingdom), the Museum Professionals Group (exists to provide a forum for its constituency of new museum professionals), the National Museum Directors’ Conference (founded in 1929 and funded by the participating institutions, provides a discussion and collaboration platform for its membership, also represents the interests of national museums to government and other stakeholders), the AIM (Association of Independent Museums), and the University Museums Group U.K. Museums in the United Kingdom also have a remarkable contingent of support and advocacy at national level in the form of specialist groups whose remit embraces a facet of museum function or issues allied to the subject of museum collections. The earliest of these is the Group for Education in Museums (1948), but their real growth came in the 1970s^[130] and relatively recent counts list more than 20 such groups.^[131] The specialist groups include: Natural Sciences Collections Association (NatSCA), Geological Curators Group (GCG), Dress and Textile Specialists (DATS), Association for Cultural Enterprises (ACE), Museum Ethnographers Group (MEG), Social History Curators Group (SHCG), Society of Museum Archaeologists (SMA), Touring Exhibitions Group, Visual Arts and Galleries Association, Museums and Galleries History Group), although today there are many more. Subject specialist networks were a key element of the *Renaissance in the Regions* report (2001), and consequently over £500,000 of Renaissance funding has been invested in existing and new specialist groups.^[132] At a regional level, professional groups exist in a country-wide network of federations. The regional federations include: South Western Federation of Museums and Art Galleries, Midlands Federation of Museums and Art Galleries, South Midlands Museums Federation, North West Federation of Museums and Art Galleries, Scottish Museums Federation, and Federation of Museums and Art Galleries of Wales.^[133]

Recognition of the need for specialized training in museum work has been extant in the United Kingdom for many years, with early initiatives following a Royal Commission investigation into the problems of the national museums and galleries between 1927 and 1930.^[134] The Museums Association took the lead in 1930 with the establishment of its Museums Diploma training, operated on a voluntary basis by experienced staff in leading national and local museums, and the first one week training course was run that year in London. In 1980, the Association released the formal teaching elements of the Diploma to the University of Leicester. Today, the Association retains control of admission to the successor to the original Diploma, the Associateship of the Association, but the future nature of this professional qualification is currently under review. The first full-time postgraduate diplomas—now Masters degrees—in Museum Studies

were introduced by the University of Leicester (1966) and then by the University of Manchester (1971), with curricula and aims based on the Museums Association's Diploma program. Nowadays many courses are offered in Museum Studies and related subjects at universities throughout the United Kingdom, and other recent initiatives by the Museums, Libraries and Archives Council have been established to encourage new entry routes into the sector.

Key Contemporary Issues

Museums have been part of the fabric of society for some considerable time in the United Kingdom, shifting to serve different generations and to satisfy the agendas of the day. The last 10 years have been particularly notable for the policy discourses of the Labour government (elected in 1997) that have "continuously layered ever greater and ever more diverse expectations onto the museum sector and museum professionals."^[135] These expectations are centered on the redefinition of museums as a public service, moving them beyond their traditional cultural role to one in which they become coordinates for change in society, resolving problems such as social exclusion (defined by the government's Social Exclusion Unit in 1997 as "a shorthand label for what happens when individuals or areas suffer from a combination of linked problems such as unemployment, poor skills, low incomes, poor housing, high crime environments, bad health and family breakdown") and orientating their work toward lifelong learning, identity and community building, public health, and economic and social integration. Initial formal articulation of the government's social inclusion expectations of museums appeared in the 1999 document *Museums for the Many*^[136] with its focus on widening access, but the broader agenda was signaled by the publication of *Centres for Social Change*.^[137] While many academics/ practitioners^[138–140] find the proactive use of museums' potential to address social problems justifiable, the coherence and feasibility of this "partly reimagined museum" have been questioned by others.^[141]

Requirements for U.K. museums to assume new roles as agents of social inclusion have rendered workforce diversity increasingly important to the sector. Although there was "explicit recognition in the early 1980s that the profession... was insufficiently diverse,"^[142] a 2006 survey by the Museums Association into the cultural diversity of staff (the Museums Libraries and Archives Council defines cultural diversity as "diversity based around ethnicity and race,"^[143] at hub museums across England identified the percentage of staff from black and minority ethnic (BME) backgrounds as 2.49%, compared with 8% of the population total, with severe under-representation in educational, interpretation and curatorial positions.^[144] These results echoed the imbalance found in an earlier report into cultural diversity at national museums by the National Museums Directors' Conference.^[145] Sandell^[142] has cited outdated workplace cultures and structures as contributory and

perpetuating factors, including a passive response to the problem, whereby under-representation is attributed to the demographic profile of a region and a lack of BME candidates for jobs ("museums do not operate discriminatory practices and... responsibility for change lies, therefore, not with the museum, but with people from ethnic minority communities, their attitudes and aspirations"),^[146] and the exclusionary corporate culture of "homosocial reproduction" (a tendency to recruit to an implicit model that reflects the existing demographics of the profession). Within the context of strategic imperatives for museums to consider diversity issues, however, recent initiatives have emerged (see, for example, the Museums Association workforce development agenda), many of which can be characterized by the use of "positive action."

Overall, the last decade has been notable for the remarkable renaissance of museums in the United Kingdom, largely made possible for English regional museums with *Renaissance* funding (see local authority museums above), and for all museum types with the financial support of the Heritage Lottery Fund (HLF). The creation of a National Lottery in 1993 and the decision not to use the principle of additionality (i.e., replace existing government spending) with the profits, but to benefit "good causes" (arts; charities; health, education and the environment; heritage, sports), has generated enormous sums of money for those causes. The good cause that has principally benefited museums is Heritage, and the HLF is the distributing body, operating across England, Scotland, Wales, and Northern Ireland. Since 1994, the Fund has awarded £4 billion to more than 26,000 projects,^[147] from tiny community events to multimillion pound capital schemes. Brown^[148] provides examples of nonnational museum beneficiaries—the Horniman Museum and the Dulwich Picture Gallery in south London, the New Art Gallery in Walsall, and the Ashmolean in Oxford, but the bold and costly national museum projects—the Tate Modern (the transformation of a disused power station on London's South Bank) and the British Museum (the iconic dome over the Museum's inner courtyard)—are perhaps the most well-known.

CONCLUSION

Guarantees about the future of U.K. museums, however, are not possible. In developing a national strategy for museums in England, Swain^[149] has emphasized that the sector is fragile and at a tipping point. Continued investment and development is seen as crucial to make a long term beneficial difference to all society. In Europe, recent trends have been for nations to reexamine their cultural legislation and strengthen legislative structures for their national heritage, in the case of museums, often creating linkages between national museums and designated regional and local institutions, articulating measures for constructive protection and guaranteeing public

access.^[150] As Babbidge^[151] notes, in the United Kingdom, *Renaissance* has begun to deliver a comparable framework for English museums but,

What is lacking is a formal status that cements the system, so that it has a long-term purpose rather than becoming another short-term initiative. It could also provide an opportunity to define a national structure that takes National museums into account, builds bridges with other parts of the heritage, and defines the core legal requirements for being a 21st century museum.

There can be no doubt that U.K. museums have made remarkable strides through free entry to the nationals, *Renaissance*, the HLF, and new methods of engagement, but long-term, joined-up, sustainable (economic and environmental) processes and vision will safeguard the nation's diverse and great cultural assets—some of the finest museums in the world.

United States: Archives and Archival Science

Cheryl L. Stadel-Bevans

National Archives and Records Administration, College Park, Maryland, U.S.A.

Danna Bell-Russel

Library of Congress, Washington, District of Columbia, U.S.A.

Abstract

The archival tradition in the United States of America consists of two components, a public records tradition and a personal papers or historical manuscript tradition. This entry will explore both traditions and their effects on the archival profession over time. It will also discuss professional development and professional organizations for American archives. It includes profiles of significant archival repositories.

INTRODUCTION

Early American colonists brought with them the habit of keeping public records from Europe. The founding generation added a strong personal papers component. These two traditions intertwined to form contemporary American archival theory and practices.

This entry will explore the history of archives in America as it descended from the English tradition; developments in the practice of archives and records management; the types of materials kept; the types of repositories that exist; professional development and training; and recent developments in the archival field.

EARLY HISTORY

Recordkeeping has long been vital to society. Knowing who was born when or who owns certain property allows for a civil society. When the European colonists came to America, they brought with them their traditions of public recordkeeping. These records would be filed with the local government or churches. They were not necessarily at that time managed as archival records, and there were no archivists *per se*. Clerks and administrators cared for the records created and filed.

The colonists who broke with England and became the founding generation of American citizens were well aware of the importance of keeping records. Their inability to access records was one of the grievances listed against King George in the Declaration of Independence.^[1] When they wrote the Constitution, they required the Congress to maintain journals. They also codified in the Fourth Amendment the right of citizens to protect their personal papers from unreasonable search and seizures.^[2] Unfortunately, this awareness did not lead them to establish proper archives or to take adequate preservation measures for government records, and many records were lost or

destroyed over time due to neglect and disasters, both natural and man-made. One exception to this is Vermont, where, in 1779, the recordkeeping responsibility was enumerated as a function of the Office of the Secretary of State.

These early Americans were also very aware of their own role in the making of the country and founded some of the earliest historical societies in the country to preserve their legacy. The earliest was the Massachusetts Historical Society, founded in 1791. Others soon followed, including the New-York Historical Society in 1804, and the American Antiquarian Society in 1812.

This began the duality of the American archival tradition wherein public records were maintained by governments and sometimes churches, while personal papers and other historical manuscripts were preserved by historical associations. From the beginning, the traditions served two fundamentally different purposes. The public records captured transactions and served a legal and administrative function. The manuscript tradition primarily served history and historians and was meant to record the achievements of a particular person or group of persons. However, at times, historical societies would also accept deposits of government records in the absence of any other formal programs for managing them.

Because historical societies saw themselves as serving history, they focused more on collecting and preserving the documents and other items that would add to the collective knowledge. Preservation and access, at least access for scholars, were key components. Early “archivists” in the historical societies were usually trained as historians.

These practices remained the same until the end of the nineteenth century. After the Civil War, the volume of records being produced greatly expanded, a pattern that would be repeated after World War II. The U.S. Congress passed the first records disposal legislation in 1889 in response. It met with limited success as agencies remained reluctant to part with their records. This was followed in

1903 with legislation to allow agencies to transfer their records to the Library of Congress (Fig. 1). Among the records transferred were those from the Continental Congress.^[3]

At the same time, the movement to establish formal state archives programs began. This was primarily led by the Southern states to preserve the Confederate legacy of the Civil War. The Alabama State Archives was founded in 1901 and was followed quickly by Mississippi in 1902. Throughout the first decade of the 1900s, many other states would also establish archives. Even Hawaii, as a territory, established its archives in 1906. New York was the most recent state to establish a program, in 1971. It is, unusually, a program of the State Education Department. It is also worth noting here that the bulk of New York's early records were destroyed in a fire in 1911.

Meanwhile, the 1880s and 1890s saw an increased emphasis on the use of primary sources in historical scholarship. To aid these efforts, many historical societies published collected works of their materials to provide for both access and a certain level of preservation of the contents through duplication. The American Historical Association (AHA) was founded in 1884 and quickly initiated several studies and committees on archives. These efforts eventually led to the establishment of the Public Archives Commission within the AHA in 1899, followed by the first Conference of Archivists held in 1909. These were formed in part to address the AHA's need to better understand and access primary source materials for historical scholarship. Also, increasingly, there was a need felt within the AHA to incorporate federal records into historical research.

Additionally, fires, always a hazard, continued to plague government agencies and their records storage. In 1877 and again in 1896, the U.S. Congress began

exploring the idea of building a Hall of Records for the storage of inactive agency records. Competing interests prevented authorization of the planning and funding for such a building until 1904. Even with funding, efforts to build a Hall of Records would again be delayed, because advocates were instead supporting the movement to build a proper National Archives for the long-term preservation and public access to records. Chief among them was J. Franklin Jameson, who would pursue this ideal until the National Archives were established.^[3]

THE MODERN ERA

The fight to establish the U.S. National Archives was a long one. The AHA created a committee on the National Archives in 1908. Authorization for the building finally came in March 1913, at the very end of Taft's administration. Unfortunately, the authorization did not include funding.^[3] During World War I, efforts and funds were directed elsewhere and no progress was made towards establishing the Archives. Once the conflict ended, congressmen wanted federal buildings located in their districts and kept resisting the building of new structures in DC without corresponding new buildings in their districts. The impasse broke in May 1926, with an omnibus buildings law that came complete with funding. It would take another 12 years before the building was finished and opened for research (Fig. 2). In 1934, the National Archives Act authorized the creation of the new executive agency to protect the records of the federal government.^[3]

In a parallel development, the Conference of Archives within the AHA continued to grow throughout the 1910s and 1920s, moving away from the historian/scholar model and more toward a true archivist model. These archivists

began to feel the need for their own association, separate from the AHA. In December of 1936, the Conference met separately for the first time, and the Society of American Archivists (SAA) was launched. SAA has held an annual meeting every year since 1937 and has published the *American Archivist* since 1938. From the beginning, it has been open for membership to archivists, rather than institutions, and during its first year had 124 members. Today, SAA has over 4000 individual members.

A third development during the 1930s was the beginning of the implementation of formal archival methods. Public records organizations, particularly the National Archives with its brand-new staff, needed better ways in which to proceed to organize the records they held.

Once again, Americans looked to the Europeans. English, Dutch, and German theories and practices were studied. As the European tradition was primarily related to public records, these newly imported methods mostly applied to government and organizational records and not to manuscript collections. Early proponents of this approach included Margaret Cross Norton, State Archivist of Illinois, and Theodore R. Schellenberg and Oliver Wendell Holmes, two prominent historians who became National Archives staff members.

Part of the appeal of the European approach for government archivists is that it brought a “scientific” methodology to the organization of records. This approach introduced the concepts of provenance and original order, which drew upon the administrative history of the records. The manuscripts tradition continued to emphasize the uniqueness of the materials and organized them by subject classification, more like library classification, to suit historical scholarship needs (Fig. 3).

The European approach also brought with it some efficiency, in particular, being able to work the records in

groups rather than at the item level. This efficiency became especially important during the 1940s. During World War II, there was an increase in the number of federal agencies as well as a quite rapid expansion in the volume of records being produced. This led Schellenberg and Holmes at the National Archives to develop the twin concepts of record group and record series. These two concepts, based on the principle of provenance, allow archivists to organize collections of records according to the administrative structures that created them. This approach had an immediate impact on government and other institutional records repositories, but it would not be adopted for use in historical societies and other manuscript collections until more than a decade later.

The World War II boom in records production was not limited to the federal government. State governments

also saw an increase in volume and many collecting repositories had increased donations or started collecting manuscripts in new areas. For example, the Sophia Smith Collection at Smith College (Fig. 4) began collecting materials related to women's history in 1942 and what is now the Schlesinger Library at Harvard University followed suit a year later.

In the post-war era, the seed of records management that began in the 1930s and grew during the 1940s came to fruition in the 1950s. By this time, records management—the systematic control of an organization's records from the records' creation through their final disposition—was seen as a discipline separate from archives, which focused only on managing permanent records. Also introduced during this time was the new field of study, information science, which used computers for collecting, storing, classifying, retrieving, manipulating, and disseminating information.

One unfortunate consequence of the focus on records management and administrative efficiency was that the National Archives was too successful at promoting it and lost its status as an independent federal agency.^[4] In 1949, the National Archives became the National Archives and Records Service, a division of the General Services Administration, the administrative agency of the federal government. It would take until 1985 for the National Archives to regain its independent status and another new name, National Archives and Records Administration.^[5]

While the 1940s and 1950s saw an increase in the growth of state archival programs, the 1960s and 1970s witnessed a rapid increase in nongovernmental archival institutions. These new institutions were primarily academic and cultural repositories. They added a new element to the archival mix, as they combined both the tradition of public recordkeeping in the form of maintaining institutional history and organizational records and the historical manuscripts traditions as they

collected materials from their communities and in support of their academic research goals.

PROFESSIONAL SOCIETIES AND PROFESSIONALISM

At various times during its history, SAA has been perceived as not meeting the needs of all archivists, and this has led to the formation of other archival associations. As records managers felt that they were focused on different tasks and duties—primarily those of current records rather than historical records—from archivists, they chose to form the American Records Management Association (ARMA) in 1955. It is now known just as “ARMA International” and consists of approximately 11,000 members.

Also in 1955, the Rare Books Section was established with the American Library Association (ALA). Its membership was drawn primarily from academic institutions. It became the Rare Books and Manuscripts Section in 1967 under guidance of Richard Berner and Arline Custer.^[6]

The 1960s witnessed the founding of the National Endowment for the Humanities (NEH) in 1965 and the establishment of the grants program of the National Historical Publications and Records Commission (NHPRC) in 1964. Since its creation as part of National Archives in 1934, the NHPRC focused on producing scholarly editions of the papers of the founding fathers. The new grants program greatly increased this work. In 1975, the NHPRC's role expanded to protect records at risk and establish archival programs. As part of this expansion, it also required the establishment of State Historical Records Advisory Boards (SHRABs). The directors of the SHRABs eventually organized into a group, one that is now known as the Council of State Archivists. Additionally, the NHPRC funded publication of SAA's first set of basic archival manuals in 1977.^[4]

The rapid growth of nongovernmental archival institutions led to many changes within the archival profession during the early 1970s. The focus of the profession shifted from managing buildings and institutions to maintaining professional identity.^[7] SAA grew larger and changed its focus, as academic archivists joined the Society and began to have a greater role in its governance. This led to some more groups splitting away. In 1972, the National Association of Government Archives and Records Administrators (NAGARA) was formed to concentrate on the issues related to governmental materials. Many regional archival associations also began during this time. These had the benefit of being smaller and local, providing more opportunities for contact within the profession. The two largest of these, the Mid-Atlantic Regional Archives Conference (MARAC) and the Midwest Archives Conference (MAC), were both established in 1972.

Until the 1970s, there was little formal academic training available for archivists. The earliest archivists would have been either historians or clerk/administrators whose responsibilities happened to include caring for records and manuscripts, and all training was done on the job. While many historians began to see the need and advocate for more formal approaches to archives management during the late 1800s and early 1900s, no formal training emerged.

It was not until the founding of the National Archives, with its immediate need for a full staff, that the awareness of the lack of training programs became more acute. The number of archivists needed prior to this was fairly small and could be drawn from the historian and librarian communities. The Archives need could not be filled by drawing on those who had already become archivists. Due, however, to the Great Depression occurring in the United States at that time, many historians and librarians were out of work, and the Archives was able to employ many of these people to create its initial staff. At the same time, the Works Progress Administration (WPA), a federal project during the Great Depression for employing the unemployed to work on public projects, hired many historians for its historical records survey. The WPA trained these people to conduct inventories of records. They looked primarily at records being produced at the state and local government level, but also included some private collections and other records. Some of the WPA-trained people would come to work for the National Archives later. Therefore, as had happened previously, most training continued to be postemployment.

Several efforts examined the training issue from different angles. Both the ALA and SAA established committees to study the educational needs of archivists. Both advocated some level of training in library methods as well as history. A few programs adopted this approach. The first academic program for archivists was established in the renowned library program at Columbia University in 1938, where a series of courses were offered.

The following year, Ernst Posner arrived from Germany and began teaching in the history department at American University. His classes, which were offered in conjunction with the National Archives, became the standard training for Archives employees for many, many years. This derailed many other needs for more formal training of archivists elsewhere. The next archival training program to be instituted in a history department would not appear until Wayne State University began offering archives classes in 1962.

Most training for archivists remained on-the-job or through an apprenticeship program. Then, in the 1970s, the number of academic programs began to expand. This paralleled the growth in awareness over professional identity within the greater community of archivists. These courses were offered in both history and library science departments, primarily at the graduate level, and were primarily taught by practicing archivists serving as adjunct faculty. During this time, the first dual degree program in both subject areas was offered by Case Western University. Unfortunately, this program no longer exists. As did many other institutions during the 1980s and 1990s, including Columbia University, Case Western University chose to eliminate its library science program.

SAA also developed its first set of guidelines on graduate archival education, which were issued in 1977. As Richard Berner points out,

While the SAA's committee [on education and training] continued its work in developing specifications for formal archival education as a subfield of an established academic discipline such as librarianship or history, the committee also addressed the well-known fact that most practicing archivists had been self-taught. Consequently, it promoted post-employment training programs.^[6]

Another important development during these decades was the recognition of the need for standardization. It began with the publication of the *National Union Catalog of Manuscript Collections (NUCMC)* in the 1950s, which "... attempted to gather standard information about archival collections from widely differing repositories and to reduce that information to a uniform catalog card format."^[4] This raised the question of how to create standards for materials that were unique and reemphasized the differences between public records and manuscript collections.

While each repository would continue to implement their own way of managing their collections, they began to use common means for description. Description standards became and continue to be an important component of the professional discourse. In addition to the *NUCMC*, archivists developed the SPINDEX system for preparing and indexing archival finding aids in the 1960s, the Machine Readable Cataloging-Archival and Manuscripts Control (MARC-AMC) format for use in library

cataloging systems in the 1980s, and Encoded Archival Description (EAD) for use on the Internet in the 1990s. In 2004, SAA released *Describing Archives: A Content Standard (DACS)*.

Much of the focus on description standards came from the availability of technology to be used as a tool in doing this work. The technology also added a new component to the archival landscape—that of electronic records. While machine-readable records had started with the first IBM punch cards, their importance as archival materials was not seen until the 1960s. The Inter-University Consortium for Political and Social Research (ICPSR) was established in 1962 to provide an archives for data users. In 1970, the National Archives accessioned its first electronic records. A conference on data archives at the 8th World Congress of Sociology in 1974 led to the founding of the professional association for data librarians and archivists, the International Association for Social Science Information Service and Technology (IASSIST). SAA offered numerous workshops on managing electronic records during the 1980s and 1990s, and these workshops continue to be in high demand today. In the 1990s, the NHPRC once again expanded its focus and established the electronic records research agenda.

During the last quarter of the twentieth century, the debate over education and qualifications for archivists continued. The need for a common professional identity in a field which did not have one path for careers, especially since SAA was not in a position to manage the accreditation of graduate archival programs, led to the founding of the Academy of Certified Archivists in 1988. Not all agreed as many archivists saw certification as a move toward a preference for technical training over a liberal arts education.^[7] SAA also updated its guidelines for graduate archival education twice during this time, in 1988 and 1994, and yet another version was released in 2002. The related guidelines for archival continuing education were adopted in 1997 and revised significantly in 2006.^[8,9]

Today, archivists continue to enter the profession from many different directions, as shown by the results of the 2005 SAA archival census.^[10] Some have received formal academic training, some participate in apprenticeship programs, others take short courses, and still others receive no formal training at all. Most archival professional associations continue to offer postemployment workshops and training to aid archivists in acquiring the skills they need for their positions.

In the 2000s, the two areas of widespread focus were digitizing materials and reducing the amount of materials in the processing backlog. The NHPRC revised its guidelines for the scope of electronic records projects; allowed for funds to be used for digitization projects; and promoted the publication of electronic editions. The federal government expanded its requirements for hiring archivists to allow archival science classes to meet the necessary education requirements. (Prior to the change,

the Office of Personnel Management's Individual Occupational Requirements for the Archivist job series only allowed classes in history, American civilization, economics, political science, public administration, and government to be counted toward the educational requirements.) There was a growing interest in the archival field as the SAA student chapters increased to 28 in number. Academic programs also began to offer online classes, and professional organizations offered online workshops.

CONCLUSION

Since the founding of the nation, archives in America have had a bifurcated nature. The first citizens kept both public records and historical manuscripts of the events occurring. These two traditions have been maintained over the intervening years, sometimes focusing on their differences and at other times embracing their similarities. Even groups that have split apart have occasionally rejoined forces, such as with the joint meeting of SAA, NAGARA, and the Council of State Archivists in 2005.

Currently the divide is most apparent in the argument over which is a better educational path to a career in archives—an advanced degree in history or library science, with a couple of institutions establishing programs that lead to an advanced degree in archival science. Some even argue that no degree is needed at all. Most agree, in very basic terms, that it is a combination of the skills one learns while doing the work and learning a certain level of archival theory that makes one trained as an archivist.

As recently as 2008, the president of the Society of American Archives questioned “whether [archivists] are a united profession” or a group divided by its distinctions. He reiterates the thought that all who “preserve the primary documentation that sustains cultural and institutional memory” should be considered part of the profession.^[11] The similarities of what archivists do should outweigh the differences.

PROFILES OF ARCHIVAL REPOSITORIES

This section provides information about many archival institutions, representing the diverse nature of archives in the United States. The repositories were chosen for a variety of reasons, including the prominence of the institution, the significance of the founding of the institution, the programmatic activities of the institution, the activities of the staff within national or regional professional associations, or the authors' familiarity of the programs. The profiles are not provided as a comprehensive or definitive list, but merely as a means to convey the breadth of diversity. Many of the institutions listed could have been placed easily into another category.

The information provided in the profiles comes directly from the Web sites of the institutions themselves. In some cases, the information has been edited for brevity and style.

National Archives and Records Administration

The U.S. National Archives was established by Congress in 1934 as an independent executive branch agency of the federal government. In 1949, it became a division of the General Services Administration and was renamed the National Archives and Records Service (NARS). In 1985, it again gained independent status and another new name, the National Archives and Records Administration (NARA).

NARA collects all of the permanent records of the federal government. It is the keeper of the Declaration of Independence, the Constitution of the United States, and the Bill of Rights. Additionally, there are at present approximately 9 billion pages of textual records; 7.2 million maps, charts, and architectural drawings; more than 20 million still photographs; over 3 million data files; and more than 365,000 reels of film and 110,000 videotapes.

At first housed in a single building in Washington, DC, NARA now has 38 facilities across the United States including 14 regional repositories and 13 presidential libraries. For fiscal year 2008, NARA had 138,167 in-person daily researchers; 377,040 public program attendees; 3,046,809 exhibit and museum visitors; and 37,806,682 online visitors. That same year, NARA received 1,221,858 written reference requests, of which 1,148,870 pertained to records at the National Personnel Records Center in St. Louis, Missouri.^[12]

NARA also provides for the management of records created by all three branches of the United States federal government—executive, legislative, and judicial. It runs a government-wide records management program that identifies records of permanent value, assures the timely destruction of temporary records, and provides federal agencies with guidance on managing their current records. The regulations for federal agencies are codified in 36 CFR §§1220-1239. Links to all of NARA's regulations may be found at <http://www.archives.gov/about/regulations/index.html>.

NARA also administers the Federal Register (FR) and the National Historic Records and Publications Commission (NHPRC). The FR is the daily newspaper of the federal government. It provides legal notice of administrative rules and notices and Presidential documents in a comprehensive, uniform manner. The NHPRC supports a wide range of activities to preserve, publish, and encourage the use of documentary sources through grants and other activities.^[13]

State and Local Government Archives

The phrase “state or local government archives” generally refers to records of permanent value created by state or

local governments, the agency that preserves those records, and the buildings in which the records are housed. While NARA is responsible for federal records management programs and archives, there is no national guidance for state, city, county, or other local government archival programs. Each state has its own regulations for programs, and local governments may institute their own additional measures.

All 50 States and the District of Columbia have archival programs. Some are managed as historical societies, some as archives, and some as divisions within other branches of state government, such as the Office of the Secretary of State or Education.

The entry on State Archives elsewhere in this volume provides more detail on these programs. The profiles below detail examples of local government archives.

Multnomah County (Oregon) Archives

The Multnomah County Archives contains records documenting county activities from its formation in 1854 until the present. Given the County's history, the bulk of the records represent the actions of the Board of County Commissioners and, after 1967, the County Chair's Office. But most departments, offices, and programs have at least some representation in the county's archival record. The archives contains roughly 950 cubic feet of records, 18,200 maps and drawings (both flat and rolled), 500 volumes, 800 recorded discs, 4750 cassette tapes, and 13,000 reels of original microfilm.^[14]

New Orleans Notarial Archives

Founded in 1867, this repository holds over 40,000,000 pages of signed acts compiled by the notaries of New Orleans, Louisiana, over three centuries. The only repository dedicated to notarial records in the United States, the materials within this repository include information on land purchases, loans, contracts, and surveys. One unique aspect of this repository is that all of the records are bound in volumes to ensure arrangement and proper housing of the records. The collections are microfilmed and the microfilm is housed at the Louisiana State archives.^[15]

San Antonio Municipal Archives Program

The San Antonio Municipal Archives Program was begun in February 2007 under the Office of the City Clerk, and in partnership with the San Antonio Public Library's Texana/Genealogy department, and the San Antonio Public Library Foundation. Prior to this date, there was no formal program or policies in place for the preservation of historical documents created by City departments. Located in the Municipal Records Facility, the program aims to appropriately house, organize, and make available for research the history of the City of San Antonio. Historical

records, aerial photographs of the city, a mayoral collection and other valuable items can be found in the City's first ever San Antonio Archives Program. The program, envisioned to possibly become a model for other municipal governments, is intended to preserve the City's historical findings.

Currently, the collection includes archived City Council minutes, ordinances, aerial photographs of the city, maps from the City Engineer and historical items such as letters from Mexican General Santa Anna.^[16,17]

Academic Repositories and Digital Projects

Archival programs in academic settings frequently include both the formal institutional archives as well as many "special collections," i.e., manuscript collections in particular subject areas as well as personal paper collections from faculty and other community members. While there are some national rules for recordkeeping based on protecting student privacy, most private academic archival programs are not regulated. Public colleges and universities must follow the requirements of their governing jurisdictions, which are usually state-issued regulations.

While government archivists have frequently been at the forefront of electronic records management, academic archivists have led efforts in digitalizing archival and library materials. They have been instrumental in creating digital libraries and digital institutional repositories.

Cornell University

Officially established in 1951, the original purpose of the Cornell archives was to document everyday life in upstate New York. This changed in 1945, when the repository acquired the Ezra Cornell Papers. These materials documented the founding of Cornell University and its establishment through the sale of Western lands. In subsequent years, the papers of the early presidents and trustees were added as were the personal and professional papers of individual faculty members.

Currently, the Archives collect and preserve records of historical, legal, fiscal, and/or administrative value to Cornell University. Holdings include official records and reports of the university, its officers, and component parts; private papers of faculty, students, staff, and alumni; official and student publications; maps and architectural records; audiovisual materials including still photographs and negatives, motion picture film, oral history interviews, and audio and video tapes; and artifacts and ephemera documenting Cornell's history.

The Cornell University Archives is part of the Division of Rare and Manuscript Collections. The Division holds 400,000 printed volumes, more than 70 million manuscripts, a million photographs, paintings, prints, and other visual media. These include collections in East Asian

history and culture, sexuality and gender, travel and tourism, and science and technology.

Cornell has also been at the forefront of developing digital collections. They have worked to provide digital surrogates of their collections and have also been involved with a number of collaborative projects with institutions such as the National Agricultural Library, the National Science Foundation, and the Massachusetts Institute of Technology to create digital collections. It is also one of the partners in the Making of America project, which is described later in this entry.

Cornell staff has also been involved with creating several programs such as the Digital Imaging Tutorial and the Digital Preservation Management Workshop and tutorial to help train archivists in how to create and preserve digital content. Cornell University staff have also written and presented extensively on digital library issues.^[18–20]

The University of Michigan

The Bentley Historical Library at the University of Michigan was established in 1935 by the University Regents to carry out two functions: to serve as the official archives of the University and to document the history of the state of Michigan and the activities of its people, organizations, and voluntary associations. The library has extensive holdings on the history of the state and the university, including more than 30,000 linear feet of archives and manuscripts, 57,000 printed volumes, 1.5 million photographs and other visual materials, and over 10,000 maps.

Collections include the Michigan Historical Collection, which documents the history of Michigan from the days of exploration to the present and the archives of the University of Michigan. The Bentley is also home to several archival training programs, which have helped shaped many leaders of the archival profession. It is also of interest that one of the former heads of the Bentley, Robert Warner, was the guiding force behind the National Archives and Records Administration becoming an independent government agency.

Moreover, in 1993, the University of Michigan library launched its first digital project. In addition to working to bring over 200 collections online, staff have helped created OAIster, a union catalog for digital collections, and the Digital Library eXtension Service, which provides the foundation and the framework for educational and non-profit institutions to fully develop their digital library collections, as well as many other projects to develop standards and provide support for digital programs. It is also one of the partners in the Making of America project.^[21,22]

Making of America

A collaboration between the Cornell University Library, the University of Michigan, and the Library of Congress,

the Making of America project provides access to digitized copies of books and periodicals from all three institutes. The initial project was a collaboration between Michigan and Cornell in the hopes of developing a collection of materials that would serve both campuses and would also document American social history in the last half of the nineteenth century. In 1999, the Library of Congress joined the project by providing access to the periodical *Garden and Forest*.

At present, Michigan has contributed 10,000 books and 50,000 journal articles with nineteenth century imprints. Cornell has contributed 267 books and 955 serial volumes. The collection is particularly strong in the subject areas of education, psychology, American history, sociology, religion, and science and technology.^[23,24]

California Digital Library

The California Digital Library, established in 1997, supports the assembly and creative use of the world's digital scholarship and knowledge. In addition, they work to improve the development and management of digital collections, innovation in scholarly publishing, and the long-term preservation of digital information. They work to improve Web capture technology; provide access to primary sources through the Calisphere project, the Mark Twain project, and the online archive of California; and to insure preservation to digital content.^[25]

Duke University

The Digital Collections Program at Duke focuses on digitizing and making available the manuscripts, rare books, documentary photographs, historic advertisements, popular music, and other materials found within the Duke Library collections. Collections include historic sheet music from the late nineteenth to the early twentieth century, historical medical images, extensive photograph collections, and material on the history of Duke University and the town of Durham, North Carolina.^[26]

Massachusetts Institute of Technology and DSpace

The archives at the Massachusetts Institute of Technology (MIT) houses the documents that tell the history of the institution, the papers of noted professors and students, books written by MIT staff and students, and oral histories of members of the MIT community. They also manage the institutions records management activities.

MIT is also the home of DSpace. DSpace was created in collaboration with Hewlett Packard so that MIT could save, share, and search its digital research materials. Released in 2002, DSpace was created as Open Source Software. It stores data in a nonproprietary format, which allows for access by users even if the original software used for the creation of the document disappears. This

allows users to customize DSpace to meet their institution needs. DSpace can capture, store, index, preserve, and redistribute the material created by scholars in digital format. It allows access to scholarly documents that have been created only in digital form and creates a searchable digital archive with documents using a variety of formats including text, images, audio and video items, and databases. It also allows for flexibility in the use of metadata, allowing users to customize DSpace to work with the policies and procedures already in place at their institutions.

The DSpace Foundation was created with other repositories around the world to study how DSpace is being used and to provide support to smaller repositories using DSpace. It also provides leadership for the DSpace community and also works to encourage wider use of the DSpace software.^[27,28]

Stanford University

Stanford University's digital collections include material drawn from throughout its collections. Included are covers from dime novel and penny dreadfuls, maps, material from the Stanford Geological Survey, correspondence from Athanasius Kircher, and the records of the General Agreement on Tariffs and Trade. Stanford has also been at the forefront of the digital library movement helping to develop standards and supporting documentation to help in the creation and support of digital collections. One of the major initiatives is the LOCKSS (Lots of Copies Keep Stuff Safe), which provides open source software to help repositories keep their digital collections safe.^[29,30]

University of Chicago

The manuscript holdings of the Special Collections Research Center of the University of Chicago Library measure 6055 linear feet and span the period from the second century A.D. to the present. Collections held by the University include the Berlin Collection acquired by William Rainey Harper in 1891; the manuscript collection of the John Crerar Library, which focuses on science and medicine; late medieval and Renaissance secular and religious texts; and commonplace books, musical scores, sermons, papal dispatches, poetry, and letters. Among the more important of the modern manuscript collections are the editorial files of *Poetry Magazine*, which contain letters and manuscripts of many leading American and English poets of the first half of the twentieth century, including T. S. Eliot, Robert Frost, Amy Lowell, Marianne Moore, Ezra Pound, Wallace Stevens, Sara Teasdale, William Carlos Williams, and William Butler Yeats; the personal papers of Poetry's editor, Harriet Monroe; and the papers of Morton D. Zabel and others associated with the publication of modern poetry, especially in Chicago.

The collections also include the papers of Stephen A. Douglass, Saul Bellow, Ida B. Wells, Julius Rosenwald, the Chicago Jazz Archive, the Illinois chapter of the American Civil Liberties Union collections, the American Association for Public Opinion Research, and the Adlai Stevenson Institute of International Affairs.^[31]

The University of North Carolina at Chapel Hill

The University of North Carolina at Chapel Hill has been at the forefront of digitizing collections focusing on North Carolina and the American South. One of their major projects has been the Documenting the American South collection. This collection provides Internet access to texts, images, and audio files related to southern history, literature, and culture. Currently, Documenting the American South includes 12 thematic collections of books, diaries, posters, artifacts, letters, oral history interviews, and songs.^[32]

Yale University

The resources held by Manuscripts and Archives include over 1700 collections of personal and family papers and organizational records that document a variety of areas, and the Yale University Archives. Originally established in 1938, the Historical Manuscripts Room served as a place to hold historical collections that did not have a home of their own.

The Yale Archives began 1906 when the staff of the Yale Memorabilia Room began to collect publications, records, and objects, particularly those related to Yale College classes. A curator for this collection was appointed in 1918, and the first university archivist was appointed in 1958. In 1961, the library established the combined position of university archivist and curator of historical manuscripts that, along with the building of the Beinecke Rare Book and Manuscript Library, led to eventual consolidation of the Memorabilia collection, the Yale Archives, historical manuscripts, and the House collections. Collection strengths include public policy and administration; diplomacy and international affairs; political and social thought and commentary; science, medicine, and the environment; legal and judicial history; the visual and performing arts; urban planning and architecture; environmental policy and affairs; psychology and psychiatry; and lesbian, gay, bisexual, and transgender history and culture. In addition, the department has extensive holdings on New Haven, Connecticut, and New England history. A recent acquisition is the Fortunoff Video Archive for Holocaust Testimonies, which holds more than 4300 testimonies providing firsthand experience of the holocaust.^[33]

Manuscript Repositories and Historical Societies

A manuscript repository is an institution that collects historical materials from people or organizations other than

itself. A historical society is a manuscript repository that focuses its collecting on a specific topic, such as a geographical area or a particular event.

The entry on Historical Societies elsewhere in this volume provides more detail on those institutions, particularly State Historical Societies. The profiles below detail examples of other types of historical societies and manuscript repositories.

Library of Congress

The Manuscript Division was one of several “departments” established in 1897 when the Library of Congress moved from the United States Capitol to a separate building nearby. In 1903, by an act of Congress and an executive order, the State Department began transferring historical papers, including several presidential collections, which had been acquired by the federal government, to the Manuscript Division.

The Manuscript Division broadly collects materials relating to political history, cultural history, and the history of science, and materials from nongovernmental organizations. At present the Division holds nearly 60 million items contained in 11,000 separate collections (Fig. 5).

The Library holds papers from 23 presidents starting with George Washington and ending with Calvin Coolidge. Some presidential papers such as the John and John Quincy Adams papers are held in repositories near their homes. Later presidential papers are held in presidential libraries overseen by the National Archives and Records Administration. The Library also holds papers of other notable governmental officials and leaders such as John Paul Jones, George S. Patton, Alexander Haig, Daniel Patrick Moynihan, and Thurgood Marshall.

The Manuscript Division serves as the archival repository for a number of nongovernmental organizations, which have significantly affected American life, including the National Association for the Advancement of Colored People, National Urban League, National American Woman Suffrage Association, National Woman’s Party, and Brotherhood of Sleeping Car Porters. Other large organizational collections include the records of the League of Women Voters and the American Colonization Society.

Additional notable collections include the papers of Susan B. Anthony, Frederick Douglass, Margaret Sanger, Luther Burbank, J. Robert Oppenheimer, Groucho Marx, Lillian Gish, Jessica Tandy, Hume Cronyn, Frederick Law Olmsted, and Ludwig Mies van der Rohe.

Though the Manuscript Division has the largest number of manuscript collections, the Performing Arts Reading Room and the American Folklife Center also hold manuscript collections.

Begun as a pilot project in 1990 to digitize materials and make them available on CD-ROM, in 1994, the Library of Congress launched the American Memory

Fig. 5 The current Manuscript Division Reading Room, Madison Building.

historical collections as the flagship of the National Digital Library Program—a pioneering systematic effort to digitize some of the foremost historical treasures in the Library and other major research archives and make them readily available on the Web to Congress, scholars, educators, students, the general public, and the global Internet community.^[34,35]

American Philosophical Society

The American Philosophical Society was created by Benjamin Franklin in 1769 to help “improve the common stock of knowledge.” Early members included doctors, lawyers, clergymen, and merchants interested in science, and also many learned artisans and tradesmen like Franklin. The Society served as the prototype for a number of other learned societies and also provided space for the University of Pennsylvania. It has provided grant funds to encourage scientific research, given awards to honor outstanding work in the sciences, and developed publications to encourage researchers to share their knowledge.

The Society houses over 7 million manuscripts within hundreds of collections of personal papers and archival materials. Collections include the papers of Benjamin Franklin, Charles Darwin, Charles Willson Peale, and Franz Boas. The collections range from the mid-eighteenth century to the present, with an emphasis on documenting anthropology and its subfields (ethnology, biological anthropology, linguistics, and archaeology), the mathematical and physical sciences, the earth sciences, and the life sciences (evolutionary theory, genetics, eugenics, biochemistry, molecular biology, and paleontology). The repository also houses over 200,000 volumes and bound periodicals and thousands of maps and prints. Many of its long series of American and foreign scientific publications are not easily available elsewhere. Rare books include first editions of Newton’s *Principia*,

Franklin’s *Experiments and Observations*, and Darwin’s *Origin of Species*.^[36]

Chicago History Museum

The Chicago History Museum is a privately endowed, independent institution devoted to collecting, interpreting, and presenting the rich multicultural history of Chicago and Illinois, as well as other aspects of American history. The Museum has over 22 million artifacts and documents. The Archives and Manuscript Division holds collections that document life in the region from 1683 to the present day, focusing on topics such as the Chicago area’s early history, social conditions and problems, twentieth-century neighborhood life, community organizations, African American history, ethnic history, women’s history, civil liberties and civil rights, politics, religious-centered social action, labor unions, environmental concerns, teachers, and school reformers. Also of interest to users will be the Studs Terkel/WFMT Oral history archives, which include audio recordings of interviews, readings, and musical programs aired during Studs Terkel’s tenure at WFMT Radio from the early 1950s through 1999. People heard on the recordings include Mahalia Jackson, Louis Armstrong, Carl Sandburg, Ralph Ellison, Dorothy Parker, and Mike Royko.^[37]

Urban Archives at Temple University

The Urban Archives was established in 1967 to document the social, economic, and physical development of the Philadelphia area from the mid-nineteenth century to the present. The Archives functions as a repository for organizational records and related materials, and as a research facility for those interested in urban studies. The Archives collections are particularly strong in areas involving social service organizations, unions, housing development, community organizations, and contain many records from

organizations involved with African Americans, education, and crime.^[38]

Military Archives

Military archives are historical societies that focus on the history of military service.

Air Force Historical Research Center

The Air Force Historical Research Agency is the repository for Air Force historical documents. It consists today of over 70,000,000 pages devoted to the history of the service, and represents the world's largest and most valuable organized collection of documents on U.S. military aviation. Included within the collection are unit histories, the papers of retired general officers and other Air Force personnel, documents from various military actions, and oral histories.^[39]

Center for Military History

The Center of Military History is responsible for the appropriate use of history throughout the U.S. Army. The Center records the history of the Army during peace and wartime. Officially this section dates back to the creation of the historical branch in 1943 and its work to preserve the history of World War II. Their work includes creating documents studying the activities of the Army, maintaining the organizational history of Army units, preserving the history of significant units during reorganizations, and providing an annual history of the Department of the Army.

The Center for Military History serves as a clearinghouse for oral history programs and also maintains its own oral history collections including end of tour interviews for staff. The Center also manages a system of 59 Army museums and 176 other holdings, encompassing some 500,000 artifacts and over 15,000 works of military art.^[40]

Naval Historical Center

As the official history program of the United States Navy, the Naval Historical Center manages the Navy Department Library, 12 Navy museums, art collections, archives, and an underwater archaeology program. The Center prepares and publishes reference, documentary, analytical, and narrative works on the history of the U.S. Navy.^[41]

Religious Archives

Religious archives are archival repositories that collect materials pertaining to religion and spirituality. These archives may be the institutional archives for a particular religious organization or group or a manuscript repository that collects material pertaining to the religious life.

American Jewish Historical Society

Founded in 1892, the American Jewish Historical Society's holdings include 20 million documents, 50,000 books, paintings, and other objects that document the contributions of the American Jewish community to life in the Americas from the sixteenth century to the present. Included within the collections are the first American book published in Hebrew and the handwritten original of Emma Lazarus' *The New Colossus*, which graces the Statue of Liberty.

The American Jewish Historical Society houses approximately 1000 archival collections, comprising 10,000 linear feet. Notable personal collections include the papers of Haym Salomon, Emma Lazarus, Henry Roth, and Stephen Wise. Organizational collections include the papers of the Council of Jewish Federations and Welfare Funds (now called United Jewish Communities); the American Jewish Congress; the National Jewish Welfare Board, the Jewish Reconstructionist Federation; Congregation Shearith Israel, New York; the Graduate School for Jewish Social Work, New York; the National Association of Hillel Directors; and the Grand Street Boy's Association.

The American Jewish Historical Society also holds photographic collections that depict the efforts of immigrant aid organizations and Jewish businesses throughout the United States. There are also images of Jewish chaplains and soldiers who served during World War I and World War II, Jewish community centers, orphanages, and synagogues.^[42]

American Jewish Archives

The American Jewish Archives, which is housed at the Hebrew Union College in Cincinnati, Ohio, holds nearly 800 major manuscript collections and over 16,000 smaller collections. The repository holds over 13,000 images. Originally founded by Jacob Rader Marcus in 1947, its goal is to provide a documentary heritage of the religious, organizational, economic, cultural, personal, social, and family life of the American Jewish community. Included within the collection are the papers of several noted rabbis, information on women within the Jewish community, and material on noted Jewish organizations and on the Holocaust.^[43]

Archdiocese of Chicago

The Archdiocese of Chicago's Joseph Cardinal Bernardin Archives & Records Center is the official repository for the records of the Roman Catholic Archdiocese of Chicago. This collection was started in 1966 by then Archbishop John Cody. The Archives has more than 8000 cubic feet of materials, making it one of the world's largest repositories of Archdiocesan Archives. Most of the material is from the twentieth century. Materials included

within this collection include the papers and photographs of former ordinaries (Cardinals: Mundelein, Stritch, Meyer, Cody, and Bernardin), auxiliary bishops, chancellors, vicar general, and the administrative records of various Archdiocesan agencies and programs. Also included are organizational papers for the Chicago House of the Order of the Poor Clares, the St. Vincent de Paul Society, the Catholic Action Federation, and the Catholic Youth Organization. The Archives houses the oral history projects for Rev. Steven Avella and Michael Hartnett.

The Archives also maintains collections of sacramental registers (pre-1916 available on microfilm), student transcripts, yearbooks, class photographs, parish annual reports, liturgical and devotional materials, cemetery records, diocesan deceased priest files, *New World* obituaries, deed and construction files, orphanage records, and architectural drawings from Archdiocesan institutions. Commemorative books are available for parishes, religious orders, diocesan clergy, and institutions.^[44]

Archives of the Episcopal Church U.S.A.

The Archives of the Episcopal Church U.S.A. is the official repository for the records of the Episcopal Church. The Archives also gathers the records of national Church bodies, the various offices of missionary program and administrative support of the Episcopal Church Center, affiliated Episcopal organizations, and the personal papers of prominent lay and ordained leaders. The Archives of the Episcopal Church is the official repository for records of the Church's General Convention, its committees, boards and agencies, and the corporate body of the national Church, the Domestic and Foreign Missionary Society of the Protestant Episcopal Church in the United States of America. Included in these umbrella bodies are the various program and administrative offices of the Episcopal Church Center in New York City. The official papers of the Primate and the Office of the Presiding Bishop are also located in the Archives. The Archives also holds the records for other churches that may no longer exist to ensure that these materials are available for future researchers.^[45]

Billy Graham Center Archives at Wheaton College

The focus of the Billy Graham Center Archives is to gather, preserve, and make available materials on the history of North American nondenominational Protestant efforts to spread the Christian Gospel. These collections include private papers of individuals, records of organizations, and hundreds of oral history interviews. These collections include the papers of the Billy Graham and the Billy Graham Evangelistic Association (BGEA) and other groups working to spread the word of the gospel around the world.^[46]

Family History Center of the Church of Jesus Christ of Latter-Day Saints

The Family History Library has the largest collection of genealogical materials in the world. Most of the records are on microfilm; other formats include microfiche, books, maps, charts, and CD-ROMs. Most of the records of the collection date from 1550 to 1920. The Family History Library had its beginnings in 1894, with the founding of the Genealogical Society of Utah. Leaders of The Church of Jesus Christ of Latter-Day Saints organized the society to assist Church members with their family history and genealogical research. Its extensive record collection is available to professional genealogists and amateur researchers alike.^[47,48]

United Methodist Church

The Archives and History Center of the United Methodist Church was officially opened on October 2, 1982, and is housed on the campus of Drew University in Madison, New Jersey. It contains a museum, a large collection of books, documents, records, photographs, and artifacts relating to United Methodist History. The purpose of the Center is "to gather, preserve, hold title to, and disseminate materials on the history of The United Methodist Church and its antecedents." The collections include the papers of some of the notable leaders of the Methodist Church and of some of churches within the denomination. Also included are recording from radio programs documenting items of interest to the community.^[49]

Business Archives

Business archives house the corporate records of the parent organization or, in some cases, are historical societies that focus on the acquisition of corporate records. The entry on Business Archives in North America elsewhere in this volume provides more detail on the history of those programs. Also included in this category are organizations that are in the business of managing archives for institutions that do not have an archival staff in-house to work with collections.

Coca-Cola

The collections of the Coca-Cola Company run from 1880 to the present day and measure approximately 2000 linear feet. At present, nearly 1200 items from the archives are on display in the World of Coca-Cola exhibit which is seen by nearly a million visitors a year. In addition to the memorabilia that is on display, the Coca-Cola Archives has administrative, financial, legal, and marketing materials.^[50]

Ford Motor Company

The Ford Motor Company Archives, which was established in 1951, is one of the oldest and most comprehensive corporate archives in the United States. The company archives contains more than 13,000 boxes of company records. The archives was started as part of the Ford Motor Company's 50th anniversary celebration. Dr. Robert Bahmer, then Assistant Archivist of the United States, developed the proposal for the archives indicating the benefits of maintaining archives to the Ford Motor Company leadership. After a very active start after the celebration of the anniversary, the Archives faced major budget cuts and was deemed not to be important. It was also suggested that material be destroyed or sent to other repositories. Though the archives did continue with limited support until the mid-1990s, it took another anniversary celebration to again focus interest on the archival collections. At that point, a professional archivist was brought on-board and work was done to help show the importance of the archives to the organization. Thanks to the work of the archivist, the Ford Motor Company began again to recognize how the archives could assist not only with anniversary celebrations but also with issues relating to many aspects of the organization including design, marketing, and legal support.^[51,52]

Levi Strauss

The Levi Strauss historical collections of documents, clothing, photographs, films, posters, advertising materials, and artifacts dates back to the mid-1800s and includes items such as the 1974 Levi's® edition of the Gremlin automobile. There are 400 linear feet of documents, including letters from Cary Grant, Henry Kissinger, Lady Bird Johnson, and Clint Eastwood; 4500 photographs; 5000 garments including the oldest pair of 501 jeans from 1879; and marketing materials including posters and different artifacts.^[53]

History Associates

History Associates Incorporated was started in 1981 when two of the founders were commissioned to write a book about the U.S. Department of Energy's response to the Three Mile Island disaster. They along with two other colleagues realized that they could help business and government leaders realize the importance of the historical materials they held. The company provides historical research and writing of company histories and other documents, managing historical records and providing records management support, and a place to store important historical records off-site.^[54]

History Factory

The History Factory started in 1979 as Informative Design Group, Inc. Originally the company planned to merge historical research with graphic design to inform and educate members of the company and the general public. This mix of archives and marketing was appealing to clients and helped them to realize the importance of their historical collections. They asked the company for assistance in preserving their historical materials.

In 1989, the company changed its name to the History Factory and in addition to the marketing work it had done in the past they began to offer archives management support and support for oral history programs. They continue to work to supply support for corporate anniversary programming, corporate history books, and heritage-based marketing and communications initiatives as well as supplying archival support and storage for their clients.^[55]

Data and Electronic Records Archives

Data archives are repositories that preserve databases and other records in electronic form that were created in a format that only a computer can process. Traditionally they have been focused on collecting data files in the social sciences and providing services that promote the secondary use of the data. More recently, electronic records archives have expanded to collect other digital formats, such as text documents and Web pages.

Inter-university Consortium for Political and Social Research (ICPSR)

Established in 1962, Inter-University Consortium for Political and Social Research (ICPSR) at the University of Michigan is the world's largest archive of digital social science data. ICPSR provides leadership and training in data access, curation, and methods of analysis for a diverse and expanding social science research community. One of ICPSR's primary activities is to provide raw data for analysis. They collect data from a variety of resources and make it available for users.

In addition to their work to provide access to data, they are also at the forefront of activities to ensure long-term access to digital data. They host the Digital Preservation Management tutorial, which helps users learn about issues involved in digital preservation and ways to deal with some of these issues, as well as hosting workshops on digital preservation.

ICPSR is also one of the leaders of the Data Preservation Alliance for the Social Sciences (Data-PASS). Data-PASS is a broad-based partnership devoted to identifying, acquiring, and preserving data at-risk of being lost to the social science research community. Examples of at-risk

data include opinion polls, voting records, large-scale surveys on family growth and income, and many other social science studies. The other leaders in the partnership are the Roper Center for Public Opinion Research at the University of Connecticut, the Howard W. Odum Institute at the University of North Carolina-Chapel Hill, the Henry A. Murray Research Archive (a member of the Institute for Quantitative Social Science at Harvard University), the National Archives and Records Administration, and the Harvard-MIT Data Center (also a member of the Institute for Quantitative Social Science at Harvard University). The project is supported by an award from the Library of Congress through its National Digital Information Infrastructure and Preservation Program (NDIIPP).^[56]

Electronic and Special Media Records Services Division, NARA

The Electronic and Special Media Records Services Division—The National Archives and Records Administration (NARA) custodial program for electronic records—began as the Data Archives Staff in 1968. The Division accessions, preserves, and provides access to electronic records of continuing value created by the U.S. Congress, the courts, the Executive Office of the President, numerous Presidential Commissions, and nearly 100 bureaus, departments, and other components of executive branch agencies and their contractors. Through these activities, NARA enables researchers to gain access to federal records designed for computer processing that federal agencies have transferred to archival custody. The holdings are as diverse as the activities and interests of the federal government and consist of more than 3 million unique files. The records may be from any type of computer applications, such as database management systems, word processing, computer modeling, or geographic information systems. The records may concern virtually any area or subject in which the Federal Government is involved, including: agricultural; attitudinal; demographic; economic and financial statistics; education; environmental; health and social services; international; military; and scientific data.^[57]

Electronic Records Archives, NARA

In the late 1990s, the National Archives and Records Administration (NARA) began work to deal with the changing nature of electronic records that were arriving from federal government agencies. NARA needed to figure out how to best manage born digital records that were not databases, including determining how best to acquire, appraise, preserve, and provide access to these materials and help government agencies learn how to deal with the lifecycle of electronic records.

In 1998, NARA began working on the Electronic Records Archives (ERA) project, with the goal of being

able to authentically preserve and provide access to electronic records created anywhere in the federal government, free from dependence on any specific hardware or software, and enabling NARA to carry out its mission into the future. After several years of conducting research in collaboration with other state and federal government agencies, computer scientists, and others to determine the problems involved with handling electronic records and to consider solutions, NARA launched the first phase of the ERA information technology system in 2008.^[58]

Minerva/Library of Congress Web Archives

The Library of Congress Web Archives (LCWA) is composed of collections of archived Web sites selected by subject specialists to represent Web-based information on a designated topic. It is part of a continuing effort by the Library to evaluate, select, collect, catalog, provide access to, and preserve digital materials for future generations of researchers. This project, originally called MINERVA, started in 2000 by collecting Web sites relating to the 2000 elections. Staff members reviewed ways to select, collect, and provide access to these Web sites. Later staff worked to capture Web sites that documented the 2002, 2004, 2006, and 2008 elections; the Iraq war; the events of September 11, 2001; the reaction to Hurricane Katrina; and the Papal transition.^[59]

Museum Archives

Archives within museums "...document the history and development of the museum, its collections, exhibitions, and programs as well as the contributions of individuals and groups associated with the museum."^[60]

Smithsonian Institution

The Smithsonian Institution Archives started in 1891. It collects the papers of the Smithsonian and of people associated with the Smithsonian. The most recent guide to the collections notes that there over 1100 record units comprising more than 15,500 cubic feet of archival material. In addition to the institutional archives of the Smithsonian, several of the museums have their own archives.^[61]

The Air and Space Museum archival collection contains approximately 10,000 cubic feet of material including an estimated 1.7 million photographs, 700,000 feet of motion picture film, and 2 million technical drawings which span the history of flight from ancient times to the present day.^[62]

The National Anthropological Archives and Human Studies Film Archives collect and preserve historical and contemporary anthropological materials that document the world's cultures and the history of anthropology. The collections include the Smithsonian's earliest attempts to document North American Indian culture, the diaries of

John Wesley Powell, and the ethnographic and linguistic research of Franz Boas, Frances Densmore, Alice Cunningham Fletcher, Albert S. Gatschet, John Peabody Harrington, and J. N. B. Hewitt. They also include early 635,000 ethnological and archaeological photographs (including some of the earliest images of indigenous people worldwide); 20,000 works of native art (mainly North American, Asian, and Oceanic); 11,400 sound recordings; and more than 8 million ft of original film and video materials.^[63]

The Archives Center of the National Museum of American History holds more than 1000 collections. They include material on advertising, music, and technology. These include original television scripts, sheet music, advertising campaign literature, and personal paper collections including Henry Tupper, the creator of Tupperware.^[64]

The Archives of American Art, open since 1954, has collected roughly 16 million letters, photographs, diaries, oral history interviews, sketches, scrapbooks, business records, and other documents that support the study of the history of the visual arts in America.^[65]

Getty Museum

The Getty Research Institute is dedicated to furthering knowledge and advancing understanding of the visual arts. The library holds over 190 collections of letters and other materials from artists and scholars such as Man Ray, Beaumont and Nancy Newhall, Paul Outerbridge, and E. Maurice Bloch.^[66]

United States Holocaust Museum

The United States Holocaust Museum, which opened in 1993, has one of the largest and most comprehensive collections of Holocaust-related materials in the world. The collections include material on Jewish life in Europe before the Holocaust; the rise of the Nazi movement; their persecution of various groups including homosexuals, Roma and Sinti (Gypsies), Jehovah's Witnesses and political dissidents; information on ghettos, concentration camps and killing centers; the liberation of Europe and the war crimes trials; and the various Holocaust memorials and commemorations around the world.

The Archives branch consists of nearly 42 million pages of records including personal papers, memoirs and testimonies of Holocaust survivors and victims, oral histories, photographs, and microfilm copies of material from countries around the world on the Holocaust. In addition, there is over 1000 hr of historical films and film clips documenting the Holocaust and World War II.^[67]

Warhol Museum

The Warhol Museum and Archives documents the work of noted artist Andy Warhol. The collection currently

consists of over 8000 cubic feet of material. This collection includes scrapbooks of press clippings related to Warhol's work and his private and public life; art supplies and materials used by Warhol; posters publicizing his exhibitions and films; over 4000 audio tapes featuring interviews and conversations between Warhol and his friends and associates; thousands of documentary photographs; an entire run of *Interview* magazine, which Warhol founded in 1969; his extensive library of books and periodicals; hundreds of decorative art objects; many personal items such as clothing; and over 30 of the silver-white wigs that became one of Warhol's defining features.^[68]

Audiovisual Archives

Audiovisual archives are collections that contain photographs, art, maps, technical drawings, sound recordings, sheet music, film, and other types of records that are primarily not textual. Detailed articles on Sound and Audio Archives and Film and Broadcast Archives may be found elsewhere in this encyclopedia.

Museum archives frequently have extensive visual materials, such as with the Smithsonian's various archives. The National Archives' Special Media Archives Division holds an estimated 8 million photographs and graphic images; over 15 million maps, charts, aerial photographs, architectural drawings, patents, and ships plans; nearly 300,000 reels of motion picture film; and more than 200,000 sound and video recordings. The Library of Congress Prints and Photographs Division has more than 13 million images, including photographs, fine and popular prints and drawings, posters, and architectural and engineering drawings.^[69]

Performing Arts Archives

A special type of audiovisual archives is the performing arts archives, which documents theatre, dance, music, and other types of performances.

Center for Black Music Research

The Center for Black Music Research at Columbia College Chicago was founded in 1983 and is the only organization of its kind. The Library and Archives of the center includes the personal papers and music manuscripts of many composers and musicians including William Grant Still, Robert Leigh Morris, and Guido Sinclair. It also includes scores donated by musicians, and the papers of the National Association of Negro Musicians and the Society of Black Composers. The collection also includes recordings covering the 1900s to the present with a focus on vernacular and popular music focus on the United States, Caribbean, South Africa, Central Africa, and Central America.^[70]

Folger Shakespeare Library

The Folger Shakespeare Library has the world's largest collection of Shakespeare materials and major collections of other rare Renaissance books, manuscripts, and works of art. The Folger opened in 1932 as a gift to the American nation from Henry Clay Folger and his wife Emily Jordan Folger. The library houses more than 256,000 books; 60,000 manuscripts; 250,000 playbills; 200 oil paintings; some 50,000 drawings, watercolors, prints, and photographs; and a variety of other materials, including musical instruments, costumes, and films.

The Folger's collection of 60,000 manuscripts range in date from the late thirteenth century to the present day, and offer a wealth of unique material relating to Shakespeare, the theater, or the early modern period. Included in the collection are letters written by the poet John Donne, prompt books for Shakespearian productions, papers of noted actor and theater owner David Garrick, and papers that document the lives of those living in the sixteenth and seventeenth centuries.^[71]

New York Public Library for the Performing Arts

The New York Public Library for the Performing Arts houses one of the world's most extensive collection of circulating, reference, and rare archival collections in its field. The music and dance collections were merged together in 1965 at the Lincoln Center. Included within the collections are historic recordings, videotapes, manuscripts, sheet music, set, light and costume designs, posters, programs, and photographs. The Dance Collection has over 1 million manuscript items documenting all forms of dance and includes the personal papers of Merce Cunningham, Vaslav Nijinsky, Rudolf Nureyev, Agnes de Mille, and Jerome Robbins. The Music Collections includes original manuscripts by Bach, Mozart, Beethoven, and Wagner as well as material from contemporary composers such as Charles Tomlinson Griffes, Louis Moreau Gottschalk, Leo Smit, Ray Green, and Andre Singer.

In addition to these collections, the repository also holds the Rodgers and Hammerstein Archives of Recorded Sound. This collection holds a variety of sound recordings from symphonic work to presidential speeches and works to ensure the preservation of recorded sound.

The Billy Rose Theatre Collection of The New York Public Library is one of the largest and most comprehensive archives devoted to the theatrical arts. Within the collections, users can find a 1767 program for a performance of *Romeo and Juliet* in Philadelphia, read a letter from Edwin Booth to his daughter, review the working script for Orson Welles *African-American Macbeth*, study costume designs from the film *Anna and the King of Siam*, analyze a videotape of *A Chorus Line*, or read scripts from current television hits. In recent years, the Theatre

Collection acquired the archives of famed theatrical producer Joseph Papp and theatre and screen star Lillian Gish. Also included within this collection is the Theatre on Film and Tape Archive, which is authorized by all of America's theatrical guilds and unions to videotape live theatre performances from across the United States. More than 4500 tapes include Broadway, Off-Broadway, and regional theatre productions; theatre-related television programs, films, and documentaries; and interviews with distinguished theatre professionals.^[72]

Popular Culture Archives

Popular culture archives document a wide range of hobbies, entertainment, and special interests in the United States.

Baseball Hall of Fame

The A. Bartlett Giamatti Research Center holds a large collection of baseball books, magazines, newspaper clippings, and archival material on baseball and related topics. The collections include historic newspapers, baseball guides, clipping files, publications created by baseball teams, contract cards for the players and archival collections including the Doubleday papers, the Mills Commission papers, the Roger Angell collection, the Garry Herrmann papers, and the Landis papers. The collections also include over 500,000 images of players, teams, stadiums, events and miscellaneous subjects and over 12,000 hours of moving image and sound recordings. The collection includes interviews, game highlights, television and radio broadcasts, animation, and music.^[73]

Brown Popular Culture Library at Bowling Green University

The Brown Popular Culture Library was founded in 1969 and is dedicated to the acquisition and preservation of research materials on American popular culture created after 1876. It is the most comprehensive repository of its kind in the United States. The manuscript collections support and complement existing print collections in the areas of popular fiction, popular entertainment, and the graphic arts. Many of the manuscripts also document the history of popular culture and pioneers in the field. These manuscript collections include literary manuscripts; movie and television scripts; dime novels; storypapers and nickel weeklies; pulp magazines; fanzines and other amateur publications; comic books and graphic novels; and posters, postcards, greeting cards, and mail-order catalogs.^[74]

Cultural Heritage Archives

The collections in cultural heritage archives illustrate the diversity of personal experiences in the United States. They document the history of ethnic and racial communities.

American Folklife Center

Originally created as the Archive of Folk Song in 1928, the American Folklife Center is one of the largest repositories of traditional life in the world. It includes over 3 million photographs, manuscripts, audio recordings, and moving images that document traditional culture from all around the world. Started by Robert Gordon, it was eventually taken over by John Lomax who traveled throughout the United States eventually with his son Alan to collect folk music. Eventually the focus of the Center expanded to include the collection of folk stories, verbal arts, and oral history. The 1976 legislation that established the American Folklife Center directs it to “preserve and present American folklife” through programs of research, scholarship, training, live performances, exhibits, publications, and preservation. The Center is involved in the Save Our Sounds project to preserve historic sound recordings and the Veterans History Project, which works to obtain firsthand account of war time experiences of veterans and those actively supporting war efforts from World War I to the present Afghanistan and Iraq conflicts. They also sponsor regular performances from groups providing traditional music and dance performances and lectures from those working to learn more about and preserve traditional folkways.

Also of note, the American Folklife Center is the custodian for the September 11 Digital Archive. This collection uses electronic media to collect, preserve, and present the history of September 11, 2001, and its aftermath. The Archive contains more than 150,000 digital items, a tally that includes more than 40,000 e-mails and other electronic communications, more than 40,000 firsthand stories, and more than 15,000 digital images. In September 2003, the Library of Congress accepted the Archive into its collections, an event that both ensured the Archive’s long-term preservation and marked the library’s first major digital acquisition.^[75]

American Heritage Center

The mission of the American Heritage Center is to preserve a clearly defined set of primary sources and rare books—reflecting the written, image, and audio history of Wyoming, the Rocky Mountain Region, and select aspects of the American past—and to make those sources accessible to all. The major collecting areas include Wyoming and the American West, the mining and petroleum industries, U.S. politics and world affairs, environment and natural resources, journalism, transportation, the history of books, and twentieth century entertainment such as popular music, radio, television, and film.

The American Heritage Center was officially established in 1945. The manuscript collections have nearly 90,000 cubic feet of historically important documents and artifacts.^[76]

Amistad Center

As the nation’s largest independent archives specializing in the history of African Americans and other ethnic groups, the Amistad Research Center is dedicated to preserving America’s ethnic heritage. The collection contains approximately 250,000 photographs dating from 1859. Literary manuscript holdings contain letters and original manuscripts from prominent Harlem Renaissance writers and poets. The manuscript collections contain over 15 million documents that record the efforts of those who have charted African American history and race relations. While about 90% of the holdings document African American history, 10% document other ethnic groups such as Appalachian whites, Asian Americans, and Native Americans.^[77]

Balch Institute, Historical Society of Pennsylvania

The Balch Institute was incorporated on April 12, 1971. The Institute collections included material documenting the immigration of southern and eastern Europeans; the records of the *Atlantis*, the first successful Greek newspaper in the United States; materials documenting Puerto Rican immigration to Harlem; the American Friends Service Committee; and the Anthracite Region Ethnic Archives Project, which started by documenting the miners especially those immigrants from the eastern and southern parts of Europe living in the Anthracite region and later expanded to include the various organizations supporting ethnic groups within the community.

As of January 2002, the Balch Institute merged with the Historical Society of Pennsylvania, and the mission and collections of the Balch have been fully integrated into the Society.^[78]

Centro de Estudios Puertorriqueños, Hunter College, City University of New York

The Centro Library and Archives is devoted to collecting, preserving, and providing access to resources documenting the history and culture of Puerto Ricans. Established in 1973 as a component of the Center for Puerto Rican Studies, the Centro Library and Archives was dedicated to activist and educator, Evelina López Antonetty in 1986. The Centro Archives, known as the Archives of the Puerto Rican Diaspora, were formally established in 1989. The collections include books, newspapers, periodicals, audio, films and videos, manuscripts, photographs, prints, and recorded music. The holdings include personal papers, records of organizations and institutions, photographic collections, broadsides, programs, and ephemera.^[79]

Clark Atlanta University

The Robert W. Woodruff Library of the Atlanta University Center, Inc., is an independent entity organized and

operating to provide an academic library for the exclusive benefit of its member institutions—Clark Atlanta University, the Interdenominational Theological Center, Morehouse College, and Spelman College. The Archives and Special Collections department houses over 7000 linear feet of manuscript collections and organizational records, and over 35,000 books, pamphlets, and other printed materials. The core of the manuscript holdings is built upon the Atlanta University Trevor Arnett Library's Negro Collection. The collections document civil rights, race relations, education, literature, visual and performing arts, religion, politics, and social work. They include the Countee Cullen/Harold Jackman Memorial Collection, and papers of Hoyt Fuller and Wayman Carver that focus on black contributions to literature, music, performing and visual arts; personal papers of scholars C. Eric Lincoln and Walter Rodney, and religious leaders Harry V. Richardson and Edler G. Hawkins; records of civil rights organizations such as the Commission on Interracial Cooperation, Southern Regional Council, and Southern Conference for Human Welfare; files documenting African American education such as the Freedmen's Aid Society, Southern Education Foundation, and United Negro College Fund.

The Atlanta University Center entered the forefront of the African-American archives with the 2006 acquisition of a historic collection of writings, sermons, and other items representing the life and work of Dr. Martin Luther King Jr. by King's alma mater, Morehouse College. The Robert W. Woodruff Library of the Atlanta University Center was designated as "custodian" of the Morehouse College Martin Luther King Jr. Collection, and charged with housing and overseeing the security and preservation of the collection. The approximately 10,000 items within this collection cover much of King's life and work between the years 1944 and 1968.^[80,81]

Heard Museum Archives

The Archives of the Heard Museum includes a wide range of materials that document Native American history, culture, and art. The materials cover all indigenous peoples of the Americas. The majority of the holdings date from the mid-nineteenth century to present. The collections emphasize Native American artists and provide context for the understanding of the museum's ethnographic and fine art collections.

The Archival materials reflect a broad spectrum of relationships and activities with Native Americans, including more than 300,000 historic and contemporary photographs. Major collections include the Fred Harvey Company photographs and papers, the R. Brownell McGrew photographs and papers, the Barry Goldwater color photography collection, American Indian Boarding School Collection, and the collections of Native American artists Pop Chalee and Joe Baker. The Archives hold approximately 300 linear feet of manuscripts, personal collections, and other cultural

materials, including more than 150 linear feet of institutional records from the Heard.^[82]

Japanese American History Archives

The Japanese American History Archives is an extensive collection of books, periodicals, documents, maps, photographs, art, and film relating to the Japanese experience in the United States from the mid-1800s to the present. Created in 1977, it provides a strong collection of material documenting the Japanese-American experience but also assists many other institutions by translating documents from Japanese to English and English to Japanese.^[83]

Moorland-Spingarn Research Center at Howard

The Moorland-Spingarn Research Center at Howard University is recognized as one of the world's largest and most comprehensive repositories for the documentation of the history and culture of people of African descent in Africa, the Americas, and other parts of the world. Its collections include more than 175,000 bound volumes and tens of thousands of journals, periodicals, and newspapers; more than 17,000 feet of manuscript and archival collections; nearly 1000 audio tapes; hundreds of artifacts; 100,000 prints, photographs, maps, and other graphic items.

The foundation of this collection was a gift from the Reverend Jesse E. Moorland who donated over 3000 books, pamphlets, and other historical materials to the University in 1914. Another major landmark was the 1946 purchase of the private library of Arthur Barnette Spingarn, who chaired the NAACP's legal committee and also served as its president. The work of developing the research center continued under the watchful eye of Dorothy Porter Wesley, the first African American woman to get a masters degree in Library Science from Columbia University. She worked for the next 43 years on the research center and the annual lecture series given at the Center now bears her name.

By 1957, the collection had added a number of collections including the papers of Alain Locke, the Joel Spingarn Papers, photographs by Carl Van Vechten, and the Oswald Garrison Villard collection of Anti-Slavery papers. Starting in 1974 work again continued to develop archival collections and the papers of Paul Robeson, Vernon Jordan, Charles Diggs, Jr., Benjamin Mayes, Charles H. Houston, and Rayford Logan were added to a growing number of collections being donated to the Center. At present, there are over 190 manuscript collections available.^[84]

Museum of Chinese in the Americas

Founded in 1980, the Museum of Chinese in America is dedicated to preserving and presenting the history,

heritage, culture, and diverse experiences of people of Chinese descent in the United States. One of the Museum's major goals is to make Chinese American history accessible to the general public, ranging from scholars to young children, from community members to international tourists.

Some of the manuscript collections include paper sculptures created by passengers of the ship *Golden Venture* while they waited in detention to find out their immigration status, material from the Chinese Musical and Theatrical Association that document the activities of the Cantonese opera clubs that flourished in North American Chinatowns from the 1930s to the present, materials documenting the life of an immigrant family who eventually created a number of major business in New York's Chinatown, and the papers of Hazel Ying Lee, a noted Chinese American woman aviator during the 1930s and 1940s.^[85]

Schomburg Center for Black Culture

The Schomburg Center for Research in Black Culture is one of the world's leading research facilities devoted to the preservation of materials on the global African and African diasporan experiences. Today, the Schomburg Center contains over 10,000,000 items and provides services and programs for constituents from the United States and abroad.

The Manuscripts, Archives, and Rare Books Division collection has grown through the years, beginning with the rare treasures from Arturo Alfonso Schomburg's personal holdings. Today, it contains more than 3900 rare books, 580 manuscript collections, and 15,000 pieces of sheet music and rare printed materials. These include the original manuscript of Richard Wright's *Native Son*; the papers of Dr. Robert Weaver, the first black U. S. cabinet officer; Gustavus Vassa's autobiography, which provides evidence for Granville Sharp's attack on slavery in the British colonies in 1796; and records of the Civil Rights Congress.

Also included within the Schomburg's collections are images from mid-eighteenth century graphics to contemporary documentary and art photographs. The more than 500,000 items include portraits of many prominent nineteenth- and twentieth-century black artists, political figures, actors, musicians, athletes, and social activists. The collection also documents black life throughout the world, including scenes from Africa and the slave era through the twentieth century Americas. Among the photographers represented are James VanDerZee, Gordon Parks, Edward Steichen, Coreen Simpson, Bert Andrews, and Chester Higgins.

The Schomburg also has a large collection of audiovisual documentation of black culture including music, oral history recordings, motion pictures, and videotapes. Included are early radio broadcasts and recordings of

statements by celebrated personalities such as Marcus Garvey, Booker T. Washington, and George Washington Carver. Musical documentation ranges from African chants to American jazz. Of special interest is the Oral History/Video Documentation Project, which videotapes interviews with historically or culturally significant figures. It offers over 5000 hours of oral history recordings and more than 5000 motion pictures and videotapes.^[86]

Women's History Archives

Women's history archives collect materials that record the contributions women have made to society. Often begun because traditional repositories only inadequately captured the efforts of women, these archives continue to focus their efforts on documenting underrepresented populations.

Sophia Smith Collection

The Sophia Smith Collection at Smith College was founded in 1942. Named for the founder of Smith College, its collections include 585 collections of manuscripts, archives, photographs, oral histories, and other primary sources documenting women's history from the colonial era to the present.

Subject strengths include birth control and reproductive rights, women's rights, suffrage, the contemporary women's movement, U.S. women working abroad, the arts (especially theatre), the professions (especially journalism and social work), and middle-class family life in nineteenth- and twentieth-century New England. Of special interest is the YWCA archives, which includes 800 boxes documenting the history of this important organization and its role in assisting racial and ethnic minorities, immigrants, and working class women.^[87]

Schlesinger Library at Radcliffe College of Harvard University

The library's origins date back to the gift of Maud Wood Park, a leader in the suffrage movement, who in 1943 donated her collection of books, papers, and memorabilia on women reformers. To honor Harvard University historian Arthur M. Schlesinger and his wife Elizabeth Bancroft Schlesinger, who were strong supporters of the mission of the women's rights collection, the library was renamed in 1965.

The library's principal holdings date from the founding of the United States to the present and include materials on the women's rights movements, feminism, health, social reform, education, professional life, volunteer and civic efforts, family relationships, and travel. Collections include the archives of Radcliffe College, the papers of Charlotte Perkins Gilman, Dorothy West, June Jordan and Pauli Murray and the records of the National Organization

for Women, 9 to 5: National Association of Working Women, the Boston's Women's Health Book Collective, and the National Association of Women Judges. The archival collections also include material focusing on the culinary arts, including the papers of Julia Child and M. F. K. Fisher.

The collections also include over 90,000 photographs, ranging from casual snapshots to the works of professional photographers as well as audiotapes, videotapes and oral history tapes, and transcripts.^[88]

Sallie Bingham Center for Women's History and Culture

The Sallie Bingham Center for Women's History and Culture in Duke's Special Collection Library acquires preserves and makes available to a large population of researchers published and unpublished materials that reflect the public and private lives of women, past and present. Collecting areas of interest include the lives of southern women, girl culture, women's sexuality and gender expressions, lay and ordained church women, and the history of feminist theory and activism.^[89]

Iowa Women's Archives

The Iowa Women's Archives holds more than 1100 manuscript collections that chronicle the lives and work of Iowa women, their families, and their communities. These personal papers and organizational records date from the nineteenth century to the present. Together with oral histories, they document the activities of Iowa women throughout the state and beyond its borders. Subjects covered include suffrage, women and sports, and the lives of women in rural communities.

Of special interest is the Mujeres Latinas project that works to preserve the history of Latina women living in Iowa. This collection includes oral histories and manuscript collections documenting those women who came to Iowa to assist with the harvest and decided to stay in the community.^[90]

Gender and Sexuality Archives

Gender and sexuality archives promote the study of human sexuality, gender identification, and reproduction.

Cornell Human Sexuality Project

In 1988, the Mariposa Education and Research Foundation donated its accumulated archive to Cornell, which formed the basis of the Human Sexuality Collection. The principal emphases of the collection are lesbian, bisexual, gay and transgendered lives, and the politics of sex.

The Human Sexuality Collection contains a wealth of information that documents women's lives, including the

emergence of the American lesbian and gay rights movement and different perspectives on the pornography business. Notable collections include the National Gay and Lesbian Task Force papers; documentation of lesbian publishing including lesbian and feminist periodicals from the 1950s to the present from across the United States, lesbian pulp novels, and contemporary lesbian erotica; oral history projects; and photographs of leaders of the gay rights movement.^[91]

GLBT Historical Society

The Gay, Lesbian, Bisexual Transgender (GLBT) Historical Society collects, preserves, and interprets the history of GLBT people and the communities that support them. The Archives and Manuscripts collection are focused on gay, lesbian, bisexual, transgender, and queer life in the wider San Francisco Bay area and Northern California. The organization works to document the tremendous diversity of GLBT life, its sexual, social, political, economic, cultural, religious, and spiritual dimensions focusing not only the lives of GLBT leaders, but also ordinary people, organizations, and informal groups.^[92]

Kinsey Institute

The Kinsey Institute at Indiana University promotes interdisciplinary research and scholarship in the fields of human sexuality, gender, and reproduction. The Institute was founded in 1947, just before the publication of *Sexual Behavior in the Human Male* in 1948. The Kinsey Institute houses extensive archival collections, including the papers of Dr. Alfred Kinsey, the records of the Institute and materials of other research scholars such as Alex Comfort, Havelock Ellis, and Albert Ellis, and organizations such as Sexual Freedom League and Society for the Scientific Study of Sexuality.^[93]

Lesbian Herstory Archives

The Lesbian Herstory Archives is home to the world's largest collection of materials by and about lesbians and their communities. Started in 1972 to ensure the preservation of lesbian culture the collection includes an extensive collection of books, newsletter and periodicals, photographs, films, diaries, posters, and oral histories. Archival collections of note include material from the Black Lesbian Study Group of New York, the Lesbian Resource Center of Seattle, and the Lesbian Avengers.^[94]

National Gay and Lesbian Archives

The ONE National Gay & Lesbian Archives honors the past, celebrates the present, and enriches the future of all lesbian, gay, bisexual, and transgender people by supporting education and research. ONE is dedicated to

collecting, preserving, documenting, studying, and communicating the history, challenges, and aspirations of gay, lesbian, bisexual, and transgender community. They collect manuscripts, photographs, memorabilia, graphics, ephemera, and other historically significant materials.^[95]

Labor Archives

A late twentieth-century phenomenon, labor archives in the United States seek to document unions and the labor movement.

George Meany Memorial Archives

The American Federation of Labor-Congress of Industrial Organizations (AFL-CIO) established the George Meany Memorial Archives in 1980 to honor the memory of its first president, and to provide a program to preserve its historical records and make them available for research. The George Meany Memorial Archives holds the records of the AFL-CIO, including administrative and staff departments, constitutional trade departments, and some federation-sponsored programs. Dating from the earliest days of the American Federation of Labor (1881), but offering almost complete records from the founding of the AFL-CIO (1955), the collections provide rich resources for historians, political scientists, trade union activists, and undergraduate and graduate students who want to examine a wide range of twentieth-century American political and social issues.^[96]

Kheel Center at Cornell University

The Kheel Center for Labor-Management Documentation & Archives was founded in 1949 as the Labor-Management Documentation Center. Its purpose is the preservation of original source materials relevant to the history of American labor unions, management theory as it applies to labor and industrial relations, and the history of employees at the workplace. The collections include 350,000 images documenting the labor movement in the twentieth century. It also includes over 19,000 linear feet of manuscript letters and documents. Included are the papers of the Amalgamated Clothing Workers of America, the International Ladies' Garment Workers' Union, the Brotherhood of Railroad Trainmen, and the National Consumers' League.^[97]

Reuther Library, Wayne State University

The Walter P. Reuther Library of Labor and Urban Affairs is the largest labor archive in North America. Its mission is to collect, preserve, and provide access to the documentary and visual heritage of the American labor movement, related reform movements, and individual participants. The collection also includes records related to urban affairs, with emphasis on the history of metropolitan Detroit.

The Reuther holds more than 2000 collections related to such topics as union history and working class organizations, African Americans and women in the labor movement, as well as radical, social, and political reform movements. Collections also focus on the history of twentieth century Detroit, including such topics as social welfare, health care, politics, civil rights, women's rights, and metropolitan Detroit social communities. The Reuther also houses the archives of Wayne State University. The collection traces Wayne State's growth from the Detroit Medical College in 1868 to its emergence as a world-class research university.^[98]

Tamiment Library and Wagner Archives, New York University

The Tamiment Library and Robert F. Wagner Labor Archives at New York University provide extensive research collections for scholarly research on Labor and the Left. The primary focus is the complex relationship between trade unionism and progressive politics and how this evolved over time. Archival, print, photograph, film, and oral history collections describe the history of the labor movement and how it related to the broader struggle for economic, social, and political change.

Tamiment/Wagner holds more than 400 manuscript collections, a total of more than 15,000 feet of original papers and records. Some of the collections include material from various locals of the Communications Workers of America, the papers of Eugene V. Debs, Elinor Ferry, Nelson Frank, and recordings of songs by Joe Glazer. It is also the repository for the Archives of Irish America, the Abraham Lincoln Brigade Archives, and a growing Asian American labor collection. The library also holds has more than 500,000 photographs documenting a wide range of subjects including: union organizing, the changing nature of work, strikes, rallies, demonstrations, progressive political campaigns, socialists, communists, anarchists, and members of other leftist organizations. They also depict working class resorts, summer camps, New York City street scenes, and architecture.^[99]

Science, Technology, and Health Care Archives

Science, technology, and health care archives collect materials relating to the natural, physical, and social sciences; engineering; technology; medicine; and health care.

Alan Mason Chesney Archives, Johns Hopkins Medical School

The Alan Mason Chesney Medical Archives is the official archival repository of the Johns Hopkins Medical Institutions. Holdings include materials from the Johns Hopkins Hospital and from the health divisions of the Johns Hopkins University (Bloomberg School of Public Health,

School of Medicine, and School of Nursing). The collections include the records of the Johns Hopkins Medical Institutions and over 200 collections of personal papers covering the years of 1900 to the present. Some of the papers include laboratory notebooks, research data, and personal diaries. Notable collections include the papers of Alfred Blalock, who pioneered the “blue baby” operation; Alan Mason Chesney, who served as dean of the medical school; W. Horsley Gantt, who explored the relationship between physiological functions and behavior; and William Osler, who established the training program used by medical students in the United States.^[100]

California Academy of Sciences

The California Academy of Science has over 400 archive and manuscript collections, and over 300,000 images. The archives includes material on the history of the Academy, research on the Galapagos Island, the Elkus Indians papers that documents Indian Affairs from 1922 to 1963, the paper of C. Templeton Crocker, Benjamin Draper, Frank Talbot, and John McCosker.^[101]

California Institute of Technology

The Institute Archives preserves the papers, documents, artifacts, and pictorial materials that tell the school's history, from 1891 to the present. The Archives houses close to 200 manuscript collections, the majority of which are the papers of Caltech's faculty and administrative officers. These include the papers of Lee A. DuBridge, Richard Feynman, George Ellery Hale, Theodore von Kármán, and Robert A. Millikan. Since 1978 the Archives has conducted an oral history program centered on the Caltech community which includes more than 150 interviews.^[102]

Charles Babbage Center

The Charles Babbage Institute is dedicated to preserving the history of information technology and promoting and conducting research in the field. The archives collects, preserves, and provides access archival collections and rare publications documenting the history of technology. Collections include the papers of the Association for Women in Computing, Edmund C. Berkeley, Martin A. Goetz, and Curt A. Monash. The Institute is also home to the historical archives of the Burroughs Corporation, once the nation's largest manufacturer of adding machines and, later, a major computer company. The collection includes over 100,000 photographs depicting the entire visual history of Burroughs from its origin as the American Arithmometer Corporation in 1886 to its merger with the Sperry Corporation to form the Unisys Corporation in 1986.^[103]

Claude Moore Library at University of Virginia

The Historical Collections and Services division of the Claude Moore Library is dedicated to the preservation and presentation of the history of the health sciences at the University of Virginia and around the world. The collection includes a large number of rare books including a collection of books on optics gathered by Adolph Lomb of the Bausch and Lomb Optical Company. Archival collections include the Philip S. Hench Walter Reed Yellow Fever Collection, which documents the work of Reed's and others to stop the spread of Yellow Fever; the papers of Henry Rose Carter, who eventually became Assistant Surgeon General of the United States; the papers of Wade Hampton Frost, who studied water pollution and established epidemiology as a field of medical research; and documents from the Blue Ridge Sanatorium, which worked to prevent and eradicate tuberculosis.^[104]

David Sarnoff Library

The David Sarnoff Library documents David Sarnoff's life; the history of radio, television, electronics, and communications; and the history of the Radio Corporation of America (RCA). Built in 1967 by RCA, the David Sarnoff Library contains a museum, the archives, and a library. Besides Mr. Sarnoff's papers and memorabilia, the Library's holdings include 25,000 photographs and thousands of notebooks, reports, publications, and artifacts related to the histories of RCA Laboratories and RCA.^[105]

Linda Hall Library

The Linda Hall Library is the largest privately funded library of science, engineering, and technology in the world open to the public. The Library has acquired several strong collections over the years including the collection of the American Academy of Arts and Sciences, founded in 1780, portions of the Franklin Institute's library, the notebooks of A. B. Nichols, who worked as an engineer on the Panama Canal, and the collections of the Engineering Societies Library.^[106]

National Agriculture Library

The National Agricultural Library Special Collection division houses rare books, manuscript collections, nursery and seed trade catalogs, photographs, and posters from the 1500s to the present. Materials cover a variety of agricultural subjects including horticulture, entomology, poultry sciences, natural history, and are not limited to domestic publications.

The Library's Special Collections houses over 300 manuscript and archival collections containing materials from the nineteenth through the twenty-first centuries.

Manuscript collections include papers of individuals who worked for or were associated with the U.S. Department of Agriculture or who were involved in agricultural activities. These collections include the papers of Charles Valentine Riley, John Wyss, and Layne R Beaty, and a small collection of Jefferson manuscripts focusing on his farming activities.^[107]

National Library of Medicine

The National Library of Medicine houses a large collection of archives and manuscripts related the history of medicine. Most of the archival and manuscript material dates from the seventeenth century and includes approximately 10,000 linear feet of material. The Library also owns about 200 pre-1601 Western and Islamic manuscripts. Significant modern collections include the papers of U.S. Surgeons General, including C. Everett Koop, and the papers of Nobel Prize-winning scientists, particularly those connected with NIH.^[108]

Niels Bohr Library and Archives and Center for History of Physics, American Institute of Physics

The Niels Bohr Library & Archives and the Center for History of Physics work to help preserve and make known the history of modern physics and allied sciences. They collect a wide variety of materials including photographs, oral histories, books, AIP, and Member Society archives. Photograph collections include portraits and snapshots primarily of modern American physicists, astronomers, and geophysicists but includes many other scientists, as well as photos and illustrations of laboratories, telescopes, accelerators and other instruments, objects, and places. There are over a thousand tape-recorded oral histories that provide information on the lives and work of noted scientists. Manuscript collections include the records of the American Institute of Physics as well as the personal papers of Samuel A. Goudsmit, Robert W. Wood, John Van Vleck, and Lew Kowarski.^[109]

United States: Libraries and Librarianship in the 21st Century

John W. Berry

NILRC: Network of Illinois Learning Resources in Community Colleges, Dominican University, River Forest, Illinois, U.S.A.

Abstract

This entry gives an overview of libraries and librarianship in the United States and explores several trends that will continue to have an impact on American libraries for the foreseeable future. These trends include: network neutrality and digital rights management; recruitment and diversity of library workers; the continuing development of the Internet; Library 2.0 and beyond (blogs, podcasts and wikis); libraries and the gaming phenomenon; librarian and library worker salaries; and library advocacy and funding.

Editor's Note: We have commissioned John Berry, an eminent library leader and former president of ALA, to contribute an entry that provides a general overview of the status of American libraries followed by a discussion of trends, issues, and technologies that impact American libraries and librarians in the first decade of the twenty-first century. His approach differs from that taken in our county entries because American libraries and library history are well represented in other entries in ELIS-3, and because most of the major library associations headquartered in the United States are covered by individual entries. Because American museums and archives are less fully covered by ELIS-3 entries, those two sections provide more historical background and discuss differences among various types of archives and museums. Beverly Sheppard, former head of Institute of Museum and Library Services, has contributed the section on Museums in the United States. The section on American Archives was prepared by Cheryl Stadel-Bevans formerly with the National Archives and Records Service and by Danna Bell-Russel with the Library of Congress. Each of the three sections has its own abstract, keywords, and reference list.

FACTS ABOUT LIBRARIES IN THE UNITED STATES

The American Library Association (ALA) estimates there are 123,291 libraries of all types in the United States in 2008 (see Table 1). No single annual survey provides exact statistics on all types of library spaces. The public, academic, and school library statistics below come from four surveys by the *National Center for Education Statistics (NCES): Public Libraries in the United States: Fiscal Year 2005; Academic Libraries: 2004 (2006); A Brief Profile of America's Public Schools (2007)* for the number of school library media centers in public schools and BIA (Bureau of Indian Affairs) schools; and the *Schools*

and Staffing Survey, 1999–2000 (2002) for the number of school library media centers in private schools. Figures for special libraries, armed forces libraries, and government libraries are from the American Library Directory 2007–2008 (Fig. 1).

ALA also reports that operating budgets in all libraries are increasing at 3–4% each year, mostly going to staff salaries, but services and collections in libraries are also increasing. Public library visits are rising, and circulation of audio and video materials have risen by 14% annually from FY 2003 through FY 2006 even as book circulations have declined substantially. <http://www.ala.org/ala/aboutala/hqops/library/libraryfactsheet/alalibraryfactsheet4.cfm>

The State of America's Libraries: A Report from the American Library Association

In April 2007, a report called *The State of America's Libraries*, published by the American Library Association found that

Public, school and university libraries are flourishing, both in traditional ways and in the still-exploding universe of the Internet. Library use is up nationwide among all types of library users, continuing a decade-long trend. Almost 1.8 billion visitors checked out more than 2 billion items last year at everything from one-room rural libraries to spectacular facilities such as Seattle's Central Library which opened in 2004.^[1]

ALA also found that the number of visits to public libraries in the United States increased 61% between 1994 and 2004.

Investment in e-books at academic and research libraries rose by 68% from 2002 to 2004, the most recent year for which federal data are available. Electronic serials expenditure has also increased at major research libraries

Table 1.

Public libraries (administrative units)		9,208
Centrals ^a	9,050	
Branches	7,542	
Buildings	16,592	
Academic Libraries		3,617
Less than four year	1,334	
Four year and above	2,283	
Total	3,617	
School Libraries		99,783
Public schools	82,569	
Private schools	17,054	
BIA (Bureau of Indian Affairs)	160	
Total	99,783	
Special Libraries^b		9,066
Armed Forces Libraries		296
Government Libraries		1,159
Total		123,129

^a The number of central buildings is different from the number of public libraries because some public library systems have no central building and some have more than one.

^b Special libraries include Corporate, Medical, Law, Religious, etc.

Source: ALA Fact Sheet 1, [http://www.ala.org/ala/aboutala/offices/library/libraryfactsheet/alalibraryfactsheet1.cfm#^{\[2\]}](http://www.ala.org/ala/aboutala/offices/library/libraryfactsheet/alalibraryfactsheet1.cfm#^[2])

and usage of electronic materials has skyrocketed. At the same time, circulation has declined slightly and reference services have declined more steeply.^{[3] [4]}

Public libraries are on the forefront in delivering new programs to their users while still providing the traditional services that people expect from their libraries—the tools to conduct a job search, write a résumé, and learn new work skills. Despite a growing body of research that links school libraries and positive student achievement, school library media centers have been hard hit by funding cuts in recent years.

The American library community continues its work to defend the First Amendment rights of library users against

secret government surveillance, including the USA PATRIOT Act passed in October 2001. Librarians also continued their efforts to oppose censorship challenges that restrict the free flow of information and ideas to both adults and children.

From Awareness to Funding: A Study of Library Support in America (2008)

In July 2008, OCLC, the world's largest bibliographic records utility, with the private market research firm Leo Burnett, published a new study of U.S. public libraries called: *From Awareness to Funding: A Study of Library Support in America* by DeRosa and Johnson.^[5]

The following are the key findings of this study:

- The American public's awareness of libraries is based on yesterday.
- The research provides important insights into what U.S. voters and their elected officials know, and what they do not know, about public libraries and public library funding.
- Most U.S. residents are aware of the traditional "informational" library services, such as books, newspapers, magazines, and Internet access.
- Far fewer know about the many value-added and "transformational" services provided by their libraries, such as teen programs, computer training, and "English as a second language" (ESL) classes.
- Support for library funding comes from those who believe libraries transform lives, and not necessarily from those who use the library.

Many American public libraries have responded by launching marketing campaigns focused on increasing

Fig. 1 Fleet library at the Rhode Island School of Design.(2007 winner American Institute of Architects/American Library Association Library Buildings Awards Program).

Source: Renovation by: office dA, Boston, MA. Photograph by: John Horner Photography, Somerville, MA.

awareness of the library and its services. Despite numerous marketing and communications efforts across the country, the perception of the library as “a physical place offering traditional information services (books and information)” remains well entrenched in the minds of library users.

And while the perceptions of the library may remain fixed, the information landscape is changing rapidly. The knowledge landscape is expanding and the library’s once unique position as the “place that provides books and information” is increasingly crowded. Powerful rivals with deeper pockets such as Google and Barnes & Noble are able to fund stronger marketing initiatives to reach information consumers and are redefining user expectations of information access. Without action, the survey argues, it is almost certain that the library’s brand will continue to be seen as a *legacy* service, a “nice to have” but not critical institution, more relevant in the past than for the future.

This OCLC sponsored advocacy research identified that residents are not aware that libraries are under financial stress. Most residents do not realize that libraries—maybe even their local library—have cut services, reduced hours or limited new material acquisitions due to reductions in their operating budgets or increases in operating costs, such as health care, collections, and utilities. On the other hand, elected officials are generally supportive and aware of the financial needs of their libraries. Those surveyed report that they are aware of the varied and important services offered by their libraries and recognize their importance to their communities. But the research also revealed that despite their appreciation for the library, local elected officials are not typically inclined to increase library funding. The majority felt that their libraries have sufficient operating funds.

If, despite the efforts of existing marketing campaigns, the library brand is still about “books and information,” the survey asks how the library can be positioned as a “transformational force” in the minds of more users and voters? If current library marketing campaigns are focused mainly on driving usage of libraries and awareness of their services, what is needed to increase library funding to inspire, and activate, residents and local elected officials to increase funding for libraries the survey asks.

Not all residents in a community are equal when marketing or advocating for increased funding for libraries. This inequality is not unexpected or unusual.^[14] As described by OCLC’s market research partner, Leo Burnett:

Not everyone is alike and different people want different things from the category. They evaluate, perceive and use brands differently.^[14] No brand has “universal appeal” and the more brands there are in a category, the more this is true. “For every brand, there is a greater chance to build business [funding] among some segments of consumers than others. If these segments can be identified, the brand

has a ‘roadmap for growth’ and can customize marketing efforts to the most likely prospects.”^[4]

The Library Supporter Segmentation Pyramid for this research identified four public library market tiers: 1) residents who are not registered or do not typically vote in elections (Chronic Nonvoters); 2) voters with high barriers to supporting the library (Barriers to Support); 3) voters who are probable library funding supporters (Probable Supporters); and 4) voters who are definite library funding supporters (Super Supporters). Within these four overarching market tiers the study made an additional 10 distinct market segments, named to reflect their distinctive characteristics: 1) Chronic Nonvoters; 2) Financially Strapped; 3) Detached; 4) The Web Wins; 5) Just for Fun; 6) Kid Driven; 7) Library as Office; 8) Look to Librarians; 9) Greater Good; and 10) Super Supporters.

The OCLC research identified several important shared values and beliefs across the target market segments, the Probable Supporters and the Super Supporters:

- They are involved in their communities.
- They recognize the library’s importance to the community and to a child’s education.
- They are not always heavy users of the library, but believe the library is a noble place, important and relevant to the community.
- They recognize the value of a “passionate librarian” as a true advocate for lifelong learning.
- They see the library as a vital community resource like public schools, fire, and police, and are willing to increase their taxes to support the library.^[5]

The survey concludes that awakening and reinforcing the transformational value of the library is the most important factor in increasing library funding support.

A successful library funding support campaign must

- Make the library relevant for the twenty-first century.
- Instill a sense of urgency by putting the library in a competitive context for funding, alongside the public schools, fire department, and police department.
- Activate conversations about the library’s importance in community infrastructure and its role in the community’s future.^[18] “To thrive tomorrow, libraries must translate belief to awareness, and awareness to action.”^[5]

Key Issues for Academic Libraries and Librarians

In its Environmental Scan 2007 (2008), The Association of College and Research Libraries (ACRL) identified the “Top Ten Assumptions for the Future of Academic Libraries and Librarians”^[6] and they include

1. There will be an increased emphasis on digitizing collections, preserving digital archives, and improving

methods of data storage, retrieval, curation, and service.

2. The skill set for librarians will continue to evolve in response to the changing needs and expectations of the populations they serve, and the professional background of library staff will become increasingly diverse in support of expanded service programs and administrative needs.
3. Students and faculty will continue to demand increasing access to library resources and services, and to expect to find a rich digital library presence both in enterprise academic systems and as a feature of social computing.
4. Debates about intellectual property will become increasingly common in higher education, and resources and educational programming related to intellectual property management will become an important part of library service to the academic community.
5. The evolution of information technology will shape both the practice of scholarly inquiry and the daily routine of students and faculty, and demands for technology-related services and technology-rich user environments will continue to grow and will require additional funding.
6. Higher education will be increasingly viewed as a business, and calls for accountability and for quantitative measures of library contributions to the research, teaching, and service missions of the institution will shape library assessment programs and approaches to the allocation of institutional resources.
7. As part of the “business of higher education,” students will increasingly view themselves as “customers” of the academic library and will demand high-quality facilities, resources, and services attuned to their needs and concerns.
8. Online learning will continue to expand as an option for students and faculty—both on campus and off—and libraries will gear resources and services for delivery to a distributed academic community.
9. Demands for free, public access to data collected, and research completed, as part of publicly funded research programs will continue to grow.
10. The protection of privacy and support for intellectual freedom will continue to be defining issues for academic libraries and librarians.^[7]

In addition, the ACRL Research Committee identified several “emerging issues” that are already of considerable local significance in academic libraries and will likely grow in importance in years to come.

- There will be broader collaboration between academic, public, special, and school librarians on topics of

common concern, e.g., public engagement, information, and media literacy.

- Pressure to make library facilities “greener” will increase. Developments in this area will likely take place as part of broader institutional efforts.
- Library facilities and services will become increasingly integrated with research, teaching, and learning programs across campus, including those housed in information technology programs and student services program.
- The library’s print materials will be moved from prime library space and relocated to off-site locations; space currently housing collections will be repurposed to support collaborative learning, new modes of research support, and interactive learning areas.
- Tensions will continue to grow each year as decisions are made that determine what portion of the budget will be used to purchase digital collections as opposed to will be used to preserve and provide access to unique collections held by the library.
- Library patrons will use semantic Web search techniques to locate information resources. The need to meet the needs of e-science and e-scholarship in the social sciences and the humanities will increase and require new approaches to the design and delivery of core library services.
- Collaboration between academic libraries and university publication programs will increase as their roles become increasingly complementary.
- The focus for academic libraries will shift from the creation and management of large, on-site library collections to the design and delivery of library services.
- Regional and professional accrediting bodies will require greater accountability using a wide range of assessment techniques.
- A crisis will occur in Library and Information Science (LIS) education as schools prepare students to assume new roles in academic libraries and as contributors to campus programs.
- Interdisciplinary studies, new models of undergraduate and graduate education, and newly developed areas of inquiry will stretch library resources and service model. The tools and techniques of social computing will provide new opportunities for the design and delivery of library resources and services, but will also make increasing demands on library staff and systems.

Librarians and Library Salaries

ALA estimates that the total number of professional librarians working in the United States is approximately 150,000 (see Table 2). The ALA Library Fact Sheet 2 notes that “the library work force includes librarians and other professionals, paraprofessionals, clerical and technical personnel.”^[7] The fact sheet summarizes the latest

Table 2 Librarian and library employees in the United States.

	Librarians	Other paid staff	Total paid staff
Academic Libraries	26,469	67,121	93,590
Public libraries	45,354	92,501	137,855
Public school libraries	50,553	30,785	81,338
Private school libraries	11,060	3,360	14,420
BIA school libraries	88	63	151
Total	133,524	193,830	327,354

Source: ALA Fact Sheet 2, <http://www.ala.org/ala/aboutala/hqops/library/libraryfactsheet/alalibraryfactsheet2.cfm>.^[7]

available statistics on the two major categories—librarians and other professionals, and other paid staff—in the three types of libraries for which reliable national figures are available from National Center for Education Statistics (NCES) and the Institute of Museum and Library Services (IMLS).

The ALA fact sheet also notes that firm numbers for those employed in special libraries (e.g., libraries serving businesses, scientific agencies, hospitals, law firms, and nonprofit organizations) are not available. However, based on information available from several related associations (such as the Special Libraries Association), ALA estimates that in 2001 approximately 15,307 librarians were employed in special libraries.

Salaries paid to librarians vary by type of library and by region of the country, and are also affected by other factors; for example salaries are usually lower in rural areas and highest in major cities. Results of the annual ALA-APA (Allied Professional Association) Salary Surveys in 2007 offer hope for advocates of higher salaries for library workers. According to the surveys, the mean salary of librarians rose faster than most estimates of inflation.

Six-figure salaries were reported for several non-MLS positions. Two surveys: *ALA-APA Salary Survey: Librarian—Public and Academic (Librarian Salary Survey)* and *ALA-APA Salary Survey: Non-MLS—Public and Academic (Non-MLS Salary Survey)* are highlighted below.

- According to *ALA-APA Salary Survey: Librarian—Public and Academic (Librarian Salary Survey)*, the mean librarian salary rose to \$57,809, an increase of \$1550 from 2006.
- Significantly, this increase of 2.8% was higher than the Consumer Price Index of 2.4% for the same time period (February 2007). The U.S. Bureau of Labor Statistics' Employment Cost Index (ECI), another measure of inflation, was between 2.4% and 3.1% for 2005, the latest figures available.^[9]

Non-MLS salary survey

The scope of the 2007 survey was expanded to include positions not requiring an ALA-accredited MLS to assess salaries of other professionals working in libraries, including accountants, human resource professionals, grant writers, and information technology staff. This data will

allow for comparisons of their salaries in the external market. Salary data are from the 2006 and 2007 *Librarian Salary Survey* and *Non-MLS Salary Survey*.^[10]

RECRUITMENT AND DIVERSITY

The U.S. Census Bureau, based on definitions from the Bureau of Labor Statistics, distinguishes between “credentialed” and “noncredentialed” librarians. Credentialed librarians are defined as librarians who report that they have completed a master’s degree or another degree higher than a master’s. The area of study is not asked in the census, hence it is inferred that librarians with a master’s degree have completed their degree in library science.^[11]

Noncredentialed librarians are all other persons whose occupation is listed as librarian but who have not completed a master’s degree. Similar degree-based distinctions are not made for library assistants or clerks.

Credentialed and noncredentialed librarians, as well as library technicians and assistants, are predominantly female, white, and are not limited by disability. This finding held true in both the 1990 and 2000 decennial census data.

Credentialed librarians are predominantly women, aged 45–54 years, and white. They are not limited by disability and work full-time (40+ hr per week). Noncredentialed librarians represent approximately 43% of those reporting for the industry “library” and have a slightly more balanced ethnic and racial distribution than do credentialed librarians. Sixteen-point-eight percent (16.8%) of noncredentialed librarians selected nonwhite race/ethnicity categories, whereas only 11% of credentialed librarians did so. Three^[14] percent more Latinos reported holding noncredentialed librarian positions, and 2% more African Americans. Other distribution differences were less than 1%. Type of library employed varies little from credentialed to noncredentialed librarians.

Library assistants are even more predominantly female than librarians, are more likely to be 35 years of age or under, and white. They, too, are not limited by disability. Unlike their librarian counterparts, they almost equally work full- and part-time weekly schedules. Type of library employed largely mirrors that reported by credentialed and noncredentialed librarians, except that higher education/academic was the second largest employer of non-MLS staff.

As American communities, urban, suburban, or rural, become more diverse in nearly every dimension, the profession of librarianship has placed more emphasis on ensuring that libraries remain in touch with the communities they serve. The ALA data suggests that libraries strategically plan around human resource development and succession planning. The persistent lag in diversity in library education programs, the number of librarians and library assistants leaving the profession prematurely, the aging and retirement of racial and ethnic minority library workers, and the continued under-representation of workers with disabilities, suggests a proportionally less diverse library workforce in the future.

Finally, the diversity study suggests that diversity should not be seen as a separate programmatic effort, but as a central framework of twenty-first century library and information science practice. “The very existence of libraries rests on our ability to create institutions and resource centers where would-be users see their information needs and themselves reflected.”^[11]

KEY ISSUES FOR ALL AMERICAN LIBRARIES

Network Neutrality and Digital Rights Management

Network neutrality (also called net neutrality, Internet neutrality, or simply NN) is a principle that is applied to residential broadband networks and potentially to all networks. A neutral broadband network is characterized by being free of restrictions on the kinds of equipment that may be attached to it, on the modes of communication allowed, it does not restrict content, sites, or platforms, and communication is not unreasonably degraded by other communication streams.

The American library community believes that intellectual freedom is critical to our democracy, because the nation relies on people’s ability to inform themselves. The growth of the Internet connecting people of diverse geographical, political, and ideological backgrounds, has greatly enhanced everyone’s ability to share and to inform both themselves and others. The American Library Association and allied associations have taken the position on network neutrality that owners and managers of the information “pipelines” should not be able to control the content nor switch some information providers to slower “lanes.” While many states are addressing this issue, there is likely to be another effort at the federal level by allied associations on one hand and the broad providers and other telecommunications service on the other.

In the context of the net neutrality debate, it is equally important that the freedom of libraries and librarians to provide innovative new kinds of information services will be central to the growth and development of a democratic culture. A world in which librarians and other

noncommercial enterprises are, of necessity, limited to the Internet’s “slow lanes” while high-definition movies receive preferential treatment is counter to a central tenet in a democratic society—the necessity of enabling educators, librarians, and, in fact, all citizens to inform themselves and each other just as much as the major commercial and media interests can inform them. The ability of the Internet to spread and share ideas is increasing rapidly. With cutting-edge technology, individuals and small groups can produce rich audio and video resources that used to be the exclusive domain of large corporations. ALA continues to support effective network neutrality policies that assure freedom of expression on the Internet and equity for all types of information providers. It is hoped that future discussions on network neutrality will be less polarized and able to reach consensus on this difficult and divisive issue. Consensus would ensure a fair distribution of Internet connectivity and speed that enables rather than restricts citizen access to the global Internet.

Digital Rights Management: A Brief Introduction

Digital Rights Management (DRM) is a term used for technologies that control how digital content is used. While copyright holders have exclusive rights of copyright—such as the right to make a copy or the right to distribute a work to the public—to date, they have not had the right to control how works are used (the right to see a work, for example, or to read a work). In addition, fair use, a statutory exemption to the copyright law, allows users to exercise a copyright under certain conditions.^[12]

Depending on the outlook of the individual or group defining the term, it can have a number of connotations including the following:

- “Digital rights management technologies are aimed at increasing the kinds and/or scope of control that rights-holders can assert over their intellectual property assets.”—*Electronic Frontier Foundation*
- “DRM must be about the ‘digital management of rights’ not the ‘management of digital rights.’”—*W3C Workshop Report on DRM for the Web*
- “The purpose of DRM technology is to control access to, track and limit uses of digital works.”—The American Library Association
- “DRM are the technologies, tools, and processes that protect intellectual property during digital content commerce. . .” —Publishers’ Requirements for DRM, *W3C Workshop Report on DRM for the Web*
- “DRM systems restrict the use of digital files in order to protect the interests of copyright holders.”—*Electronic Privacy Information Center*^[13]

The well-established user privileges in the analog environment are generally seen as threatened by DRM in the American community. Copyright owners have acted in

response to the proliferation of digital content, where the 1000th copy is identical to the first. In terms of distribution, the Internet now enables instantaneous distribution of digital content across a global network moving content owners and users into a new arena where each is adjusting to ensure, assert, and in some cases, enhance their rights. Content owners are looking to DRM technologies as a means to control the use of their content. Many public interest organizations, including the leading U.S. library associations, fear that DRM technologies will be “used by copyright owners to erode capabilities that had previously been permitted to the public by copyright law under the ‘fair use’ doctrine (or its cousins, such as first sale or limited term).”^[14]

DRM technologies can also be used for unethical and illegal activities including infringing on privacy, personal profiling, and price discrimination based on personally identifiable information and obstructing the development of open source software. For libraries, DRM technologies can additionally impact first-sale, preservation activities, and institute pay-per-use pricing.

The entertainment industry, led primarily by the Motion Picture Association of America (MPAA) and the Recording Industry Association of America (RIAA), is actively pursuing DRM-friendly policy initiatives through federal legislation and regulations, the courts, and standards organizations. The consumer electronics and the information technology industries are also joining the debate because their products would need to be redesigned to meet entertainment industry needs. Profits, business models, and the implications of technology mandates are driving this part of the debate. Meanwhile, libraries, educational institutions (K-12 and higher education), and consumers will be heavily affected by any decisions made by the federal government, courts, and standards bodies. Public advocacy groups have broadened the policy debate to include user rights such as privacy, fair use, first-sale, and preservation.

Gaming in Libraries

The library field is seeing all types of libraries adding the phrase “gaming and libraries” to their array of services.

A 2007 issue of *Library Technology Reports* examined the growing, and increasingly visible, intersections the library profession has with the gaming phenomenon.

Historically, gaming and games have been central to leisure and learning activities in societies since ancient times. Sumerian games, ancient Egyptian games, medieval games, turn-of-the-century games, and contemporary games all have threads in common:

- Games test problem-solving skills.
- Games are inclusive.
- Games create community.
- Games facilitate learning.

- Games provide fields for practice of leadership and team skills.
- Games develop identity.^[14]

Since the beginning of the twenty-first century, college and university courses, departments, and academic fields have been formed to study video games, and educators and librarians, and health care professionals are examining ways to incorporate these threads into schools, universities, hospitals, and nursing homes. A growing contingent of librarians are creating new intersections of services, where libraries can meet and serve gamers.

In mid-2008, the American Library Association launched an innovative project to track and measure the impact of gaming on literacy skills and build a model for library gaming that can be used nationally. Funding for the project is a \$1 million grant from the Verizon Foundation, justifying such a project by that: “Gaming is a magnet that attracts library users of all types and, beyond its entertainment value, has proven to be a powerful tool for literacy and learning.”^[15]

As part of the grant, ALA will work directly with 12 leading gaming experts to document the use of gaming as a literacy tool and monitor the results of gaming initiatives. The information will be used to build “The Librarians’ Guide to Gaming,” a comprehensive, online literacy and gaming toolbox, which will then be field-tested by several libraries.

The experts creating the best practices during the initial phase of the project are from 14 libraries across the United States.

Web 2.0 and Library 2.0

Web 2.0 is a term used to denote several different concepts:

- Web sites based on a particular set of technologies such as AJAX (Asynchronous JavaScript and XML).
- Web sites which incorporate a strong social component, involving user profiles, friend links.
- Web sites which encourage user-generated content in the form of text, video, and photo postings along with comments, tags, and ratings.

Some sites are easy to classify: social networking sites such as Facebook and MySpace are often held up as prototypical examples of Web 2.0, primarily due to their social networking aspects which include the user as a first-class object, but also due to their use of new user interface technologies (Facebook in particular). Other sites are resolutely Web 1 in their approach: Craigslist, for example, emulates an e-mail list server, and has no public user profiles, or fancy dynamic pages.

The term Web 2.0 was coined in 2004, and many of the first truly Web 2.0 sites began emerging in late 2003 and

early 2004. A definition of Web 2.0 by O'Reilly (2005) emphasizes viewing the Web as a platform. Some of the important features that mark out a Web 2.0 site include:

- Users as first class entities in the system, with prominent profile pages, including such features as age, sex, location, testimonials, or comments about the user by other users.
- The ability to form connections between users, via links to other users who are “friends,” membership in “groups” of various kinds, and subscriptions or RSS feeds of “updates” from other users.
- The ability to post content in many forms: photos, videos, blogs, comments, and ratings on other users’ content, tagging of own or others’ content, and some ability to control privacy and sharing.
- Other more technical features, including a public API to allow third-party enhancements and “mashups,” and embedding of various rich content types (e.g., Flash videos), and communication with other users through internal email or IM systems.^[16]

Library 2.0 Defined

The term Library 2.0 was coined by Michael Casey on his blog LibraryCrunch as a direct spin-off of the terms Business 2.0 and Web 2.0. Casey suggested that libraries, especially public libraries, were at a crossroads where many of the elements of Web 2.0 had applicable value within the library community, both in technology-driven services and in nontechnology-based services. In particular, he described the need for libraries to adopt a strategy for constant change while promoting a participatory role for library users.^{[17] [18]}

Library 2.0 made its conference debut at Internet Librarian 2005 when Michael Stephens, then of Saint Joseph County Public Library (IN) addressed the idea in relation to the typical library Web site. With Library 2.0, library services are frequently evaluated and updated to meet the changing needs of library users. Library 2.0 also calls for libraries to encourage user participation and feedback in the development and maintaining of library services.

The active and empowered library user is a significant component of Library 2.0. With information and ideas flowing in both directions—from the library to the user and from the user to the library—library services have the ability to evolve and improve on a constant and rapid basis. The user is participant, cocreator, builder, and consultant—whether the product is virtual or physical. Library 2.0 has been a source of debate in the blogosphere. Some librarian bloggers have argued that these key principles are not new and have been part of the service philosophies of many library reformers since the nineteenth century. Others are calling for more concrete examples of how libraries can get to Library 2.0.

Proponents of Library 2.0, such as Stephen Abram, Michael Stephens, Paul Miller and others, have spoken to these criticisms, arguing that while individual pieces of Library 2.0 may not be entirely new, the convergence of these service goals and ideas with many new Web 2.0 technologies has led to a new generation of library service.

Libraries are exploring ways to meet the rapidly changing needs of users by using Web 2.0 technology. Some of the aspects of Library 2.0 include commenting, tagging, bookmarking, discussions, using social networking software, plug-ins, and widgets. Inspired by Web 2.0, it is an attempt to make the library a more user-driven institution.

Blogs and Blogging

A blog (a shortened form of “Web log”) is a Web site, typically maintained by an individual, with regular entries of commentary, descriptions of events, or other material such as graphics or video. Entries are commonly displayed in reverse-chronological order. Blog can also be used as a verb, meaning to maintain or add content to a blog.

Many blogs, including several in library and information sciences, provide commentary or news on a particular subject; others function as more personal journals or diaries. Blogs combine text, images, and links to other blogs, Web pages, and other media related to its topic. The ability for readers to leave comments in an interactive format is an important part of many blogs and what makes them part of Web and Library 2.0. In December 2007, the blog search engine *Technorati* was tracking more than 112 million blogs worldwide.^[19]

Podcasts

A podcast is a series of digital media files distributed over the Internet using syndication feeds for playback on computers and portable media players. The term podcast, like broadcast, can refer either to the series of content itself or to the method by which it is syndicated; the latter is also called podcasting.

Though podcasters’ Web sites may also offer direct download or streaming of their content, a podcast is distinguished from other digital media formats by its ability to be syndicated, subscribed to, and downloaded automatically when new content is added, using an aggregator or feed reader capable of reading feed formats such as RSS (Really Simple Syndication).^[20]

Wikis

A *wiki* is a collection of Web pages designed to enable anyone who accesses it to contribute or modify content, using a simplified markup language. Wikis are often used to create collaborative Web sites and to power community Web sites. The collaborative encyclopedia, Wikipedia, is one of the best-known wikis. Wikis are used in business to

provide intranets and Knowledge Management Systems “Wiki” (/wiki/) is originally a Hawaiian word for “fast.”^[20]

Taken together, blogs, podcasts, and wikis, along with social networking sites, make up the digital framework for Library 2.0.

Library 2.0 Debates

Although many libraries are adopting features of the new social networking of Web 2.0, it is not yet clear how these new features will be incorporated into existing library services. In a program preceding the 2008 American Library Association Annual Conference, the Urban Libraries Council (ULC) brought together library directors, managers, and young librarians to consider transformational trends in learning and social networking that demand faster library innovation. “In an era of Google, what do libraries become?” asked ULC’s “virtual” scholar Jeff Garreau, a scenario planner and author of *Radical Evolution*.

John Seely Brown, author of *The Social Life of Information*, discussed the notion of twenty-first century literacy—“that technologies are central to success”—and the shift from “I think therefore I am” to “We participate, therefore we are” and “I am what I produce and other people build on.” Two other invited panelists who had been expected to endorse those ideas challenged Brown’s social learning construct. Owen Wasow, cofounder of BlackPlanet.com, contradicted Brown, saying that core skills—reading, writing, math—are key to success. “Technology should be subservient to higher goals,” he said. J.C. Herz, *Joystick Nation* author and founder, emphasized libraries as “the social space around content,” especially books, and urged librarians to be “the network (or community) around books.”

A third panelist, Joe Janes, University of Washington I School Associate Dean, said that “digital neighborhoods are bereft of the services and resources we represent. How do you provide that service?” One answer might be in the new values for the profession Janes proposed: “collaboration, participation, interaction, creativity, connectivity and connectedness, openness, vision, reflection, and play.”^[21]

CONCLUSION

Libraries and librarianship in the United States have an exciting and challenging future—a future that is driven both by traditional collections and services and by an expanding array of new, largely technology-based materials and services. The fundamental nature of the library and information space in this century will continue to be influenced by the global Internet, savvy technology companies with deep financial resources, and agendas for continuing growth and expansion. Web 2.0, Library 2.0, and their future iterations will also determine, in large part, what future libraries will be.

Funding is a central issue for all types of libraries, especially those in the public sector. Library supporters will need to use sophisticated advocacy and marketing strategies to maintain and increase support from government officials and community leaders and build partnerships and collaborative relationships with the private sector.

The possibilities of libraries being widely perceived as a nonessential legacy service are very real. Dynamic and creative leadership by the next generation of library leaders is essential to ensure that libraries will not only serve users for the foreseeable future, but also increase their role in the education of users with skill sets appropriate to twenty-first century global citizens.

United States: Museums

Beverly K. Sheppard

Institute for Learning Innovation, Edgewater, Maryland, U.S.A.

Abstract

America's museums are among the nation's most important cultural assets. These museums are remarkably diverse in size and discipline and increasingly reflect the issues, diversity, and complexity of their communities. American museums are highly professionalized, working within well-defined standards with well-trained, specialized staff. National leadership and support for museums comes through the American Association of Museums, the Institute of Museum and Library Services and numerous discipline-based professional associations. The museum field today works more closely with the public and communities than ever before, reflecting a trend toward accountability, collaboration, and the creation of public value.

INTRODUCTION

America's museums are among the nation's most important cultural assets. Although no current census of museums exists, the American Association of Museums (AAM) estimates approximately 17,500 museums are located across the country, in communities of all sizes.^[1] These institutions are both collecting and non-collecting institutions that share a common mission of service to the public. The majority of American museums are nongovernmental (privately operated) organizations, governed by boards of trustees, incorporated within their states of residence and operation, and given exemption from payment of federal taxes, with approval from the Internal Revenue Service. There are also a number of museums that are supported at least in part by municipal, state, or federal entities.

America's best known museums are its large urban institutions, such as the Metropolitan Museum of Art and Museum of Modern Art in New York City, the Field Museum and Art Institute in Chicago, and the Getty Museum in Los Angeles. The Smithsonian Institution in Washington, D.C. is a full campus of world class museums, and many other cities, such as Baltimore, Atlanta, Philadelphia, and Boston offer urban aquariums, zoos, science centers, history museums, art museums, and children's museums as part of their rich assemblage of distinguished museums. Small museums, located in America's small towns and rural areas make up as many as 75% of the nation's museums.^[1] Their collections often represent local and regional history.

American museums are remarkably diverse. They include art museums, history museums and historic sites, children's museums, museums committed to science and technology, natural history museums, zoos, aquariums, botanical gardens, and arboreta. The increasing number of ethnically specific museums—museums focusing on the history of such groups as African Americans, Latinos,

and Asian Americans—demonstrates America's current interest in building museums to preserve and share diverse cultural developments and contributions.

DEFINITIONS

The *Code of Ethics for Museums*,^[2] written by the AAM identifies the common denominator of all types of museums as making a "unique contribution to the public by collecting, preserving, and interpreting the things of this world." Recent publications, such as AAMs *Excellence and Equity*,^[3] further stress the importance of the educational purpose of museums, asserting that education should be specifically identified in every museum's mission statement.

The federal government, in the Museum and Library Services Act,^[4] defines a museum as, "A public or private nonprofit agency or institution organized on a permanent basis for essentially education or aesthetic purposes, which, utilizing a professional staff, owns or utilizes tangible objects, cares for them, and exhibits them to the public on a regular basis." This definition provides the criteria for federal funding to museums as administered by the Institute of Museum and Library Services (IMLS).

Further criteria for federal funding require that a museum must:

- Be organized as a public or private nonprofit institution that exists on a permanent basis for essentially educational or aesthetic reasons.
- Care for and own or use tangible objects, whether animate or inanimate, and exhibit these objects on a regular basis through facilities that it owns or operates.
- Have at least one professional staff member or the full-time equivalent, whether paid or unpaid, whose

primary responsibility is the acquisition, care, or exhibition of the public objects owned or used by the museum.

- Be open and provide museum services to the general public for at least 120 days a year.

BRIEF HISTORY

Charles Wilson Peale founded America's first museum in 1786. Peale, an artist, scientist, and Revolutionary War officer and patriot, opened his eclectic museum in Philadelphia. Its contents included living species of toads, lizards, snakes, and other amphibians, along with his collection of stuffed and mounted animals. He eventually included the entire skeleton of a mastodon which he helped excavate from a farmer's field in upper New York State. Peale exhibited his natural and scientific curiosities and collections alongside many of his own paintings, including an extensive collection of miniatures of Revolutionary War officers. Peale's painting, *The Artist in his Museum*, completed in 1822, is a self-portrait of Peale lifting a heavy velvet curtain to reveal the wonders exhibited inside. In 1806, Peale also founded the Pennsylvania Academy of Fine Arts, the nation's first art school. His emphasis on education, both in the museum and the art school, may have set in motion the educational role that museums continue to pay today.

The nineteenth century was America's first great era of museum building. Museums became the handsome symbols of a growing civic pride. Historical societies opened in large and small towns, celebrating their community's founders and collecting icons of local accomplishment. The Smithsonian Institution, dedicated to "the increase and diffusion of knowledge," was founded in 1846 and became an integral part of the nation's capitol. The first American zoo opened in Philadelphia in 1854, the first botanical garden in Washington, D.C. in 1850, and the first children's museum in Brooklyn in 1899. Museums created after the Civil War quickly developed into models of professional museums—with their objects displayed in an orderly and purposeful manner. Private collections became public, and art collections, housed in magnificent urban temples, proved that American cities could compete as world-class cultural centers. Individuals such as Henry Frick and Isabella Stewart Gardner provided the contents of their homes to be converted into museums for the public. The 1870s also witnessed the founding of such great institutions as the Museum of Fine Arts in Boston, the Metropolitan Museum of Art, and the Philadelphia Museum of Art. The power and wealth of their benefactors could be seen in every aspect of their majestic facades and their world famous collections.

The work of these early museums focused on collections, scholarship and cultural authority, developing world standards in collecting, researching, conserving, and managing collections. An educational mission was also present

early on, and the school field trip became a core practice, acknowledging museums as places that could open new worlds to all who visited. Throughout this early era, enormous personal philanthropy built America's great collections and museums. Even today, individual and foundation giving remains the cornerstone of museum finances. An array of government entities, including such national agencies as the IMLS, the National Science Foundation, the National Endowment for the Arts, and the National Endowment for the Humanities, provide some funding in support of museum programs, exhibits, conservation, and research. However, most museums rely far more substantially on private funding and earned income.

Museum building continued during the twentieth century. Indeed, as many as half of the nation's museums have been started since 1960. Many of the country's small historical societies developed in response to the bicentennial celebrations in the 1970s when American history took center stage. Science centers and children's museums have shown considerable growth in recent years, providing new ideas about interactive and experience-based learning. They parallel a contemporary interest in and concern about science literacy, early learning opportunities and learning outside the classroom. As noted, many special interest and special purpose museums, such as those chronicling Native American, African American, and gay and lesbian history and culture have contributed in recent years to the diversity of American museums. Such great variety of museums suggests that Americans see museums as places that offer significant ways of encountering and understanding a complex world.

During this same period, many American museums took on broader social responsibilities. Zoos, for example, quickly changed from "menageries" to educational displays of animals in natural habitats. In the last 40 years, they have become centers of learning, promoting conservation, and education about all forms of animal life. Similarly, botanical gardens have expanded their missions—building campuses of public gardens, classrooms, and research facilities to share issues of biodiversity and a threatened natural world.

Children's museums and science and technology centers have been clear about their educational mission from their beginnings. Just as Americans delighted in their discoveries of scientific wonders and technology at the Philadelphia Centennial Exposition of 1876, they quickly became captured by such major institutions as the Museum of Science and Industry in Chicago and the National Air and Space Museum in Washington, D.C. Science and technology centers have become increasingly prominent across the country and are among the most interactive of America's museums, inviting learning in a direct and engaging manner. More than 100 science museums opened their doors in the 1990s. With a similarly direct educational mission, children's museums also are now the fastest-growing sector of the museum community.

American museums were seeing unparalleled attendance and growth in the late twentieth century. Numerous studies in the late 1990s depicted a lively and prosperous time for museums. Statistics gathered by the AAM^[5] suggested that American museums welcomed approximately 865 million visits a year, a total that reflected a 50% increase over the previous decade. Thirty-six percent of travelers surveyed noted that their travels would include a museum destination. In addition to providing exhibits and programs for general visitors, museums were also increasing their school services. A study from the IMLS determined that 88% of museums actively provided programs for students from kindergarten through the 12th grade, and many of those also provided specific educational offerings for teachers.^[6]

The optimism of the twentieth century, however, was decidedly interrupted by the events of September 11, 2001, and the subsequent financial downturns that rocked the nation and the world. The bright museum reports of the 1990s have been replaced in recent years with serious reports of increasing debt, declining attendance, critically deferred maintenance, and overstretched government and private funding sources. The events of a dramatically changed era are also changing museums and forcing renewed thinking about museum missions and purposes in an altered world. As a result, new attention is being given to such topics as community collaboration, renewed educational emphasis, new approaches to the use of technology, and the role of museums in creating public value.

HOW MUSEUMS OPERATE

Museums may be public or private, university-owned or controlled, owned by a government entity, such as a city or country, or organized as part of a larger cultural complex. The majority of museums are not-for-profit entities. Their business models are structured to provide public services and benefits, rather than to make financial gains for their shareholders. They require Boards of Trustees or Directors who maintain the financial oversight as well as responsibility for establishing the policies that guide the institutions.

Day-to-day operations are managed by professional museum staff, trained to manage finances, maintain collections, undertake research, develop exhibits, plan educational programs, and communicate with the public. Staff positions may include administrative and financial personnel, curators and registrars, conservators, scholars, educators, exhibit designers, and an array of support personnel. Museums are guided in their work by institutional mission statements. Museum missions generally speak to collecting, preserving, exhibiting, and interpreting with a focus on providing value for the public.

Museum directors are their institution's chief executives. The director manages the day-to-day operations of

the museum, sets operational goals and objectives, oversees personnel and reports to a Board of Directors. Directors may come from many different backgrounds. Increasingly, directors are stepping into their leadership roles from the world of business rather than scholarship. While for many years, directors exhibited strong academic backgrounds in the subject areas of their institutions, such as art history, zoology, botany, or history, Boards of Trustees, responsible for hiring the chief executive, have begun to look outside of academic disciplines, seeking administrative and financial experience.

Recently, the director's role has become more heavily focused on fundraising and financial management. Some institutions, such as the Philadelphia Museum of Art, have experimented with dividing the leadership roles between an artistic director and a business administrator. Others now routinely hire a Chief Operating Officer (COO), taking another model from the business sector. The COO manages the day-to-day operations while the Director focuses on fundraising and key policy issues.

The decade of the 1990s and the early twenty-first century, has been a time of great change in museums, leading them increasingly toward greater self-sufficiency as business enterprises. The museum director in this changed environment now needs to demonstrate a breadth of leadership skills, not unlike those found in the for-profit business world. Financial and marketing acuity are essential to make certain that the museum survives in a new, competitive, and global marketplace.

The curatorial positions in a museum are highly specialized. They require significant subject matter scholarship, as well as deep knowledge of issues related to the care of collections. In an art museum, for example, there may be a curator of twentieth century art, of prints and drawings, of European art, Asian art, etc. The largest of museums will have many different curators, each responsible for specific collections. It is not uncommon for a small museum, however, to have a single curator, who oversees all collection functions.

Curators, registrars, and conservators share important responsibilities for the management of collections. Curators are generally responsible for undertaking collection research and acquisition, developing object provenance, maintaining collection records, and making certain collections are properly cared for and preserved. Registrars are highly specialized members of the curatorial staff who oversee all aspects of record keeping and collection management. Conservators assess, maintain, and repair artifacts of all kinds. They are the museum's specialists in advising on and establishing the optimal conditions for collection storage.

Curators are often the primary exhibit developers. Their knowledge of subject matter and objects within a collection is the creative force behind most museum exhibitions—the primary educational vehicles that enlighten visitors with fresh information and insights related to a

central theme and illustrated through objects and text. Thus, the curators are often the creative “authors” of the exhibit content.

In most museums today, however, curators do not work alone on the design and development of exhibits. Many museums routinely work in exhibit teams, groups of staff that represent the various perspectives that connect the exhibition to its audience. The exhibit team will often include members of the museum education staff, marketing staff, exhibit designers, and evaluators, each of whom brings a specific expertise to the process. Museum educators, for example, are becoming increasingly important in museums, charged with the primary responsibility of understanding how people learn in informal settings and representing the public perspective throughout the exhibit development process.

The educational role of American museums took on new importance with the 1992 report *Excellence and Equity: The Public Dimension of Museums*, published by the AAM.^[3] This landmark report stressed the educational dimension of every area of a museum’s practice, encouraging all museums to integrate their educational purpose in their mission statements, and to enhance their ability to reach diverse audiences with rich opportunities for life-long learning. With this report, the role of museum educators grew dramatically in importance.

Museum educators specialize in understanding how people learn in informal settings. Their responsibilities are to ensure that exhibit design, way-finding, programs, and special activities incorporate current educational theories and optimal learning experiences. Educators may specialize in student audiences, working closely with schools, or they may focus on adult or family learning, program development or the development of teaching materials. Museum educators are expected to be deeply knowledgeable about both content and theory and should oversee their applications within the museum setting.

Other departments within museums include:

- Public information offices, responsible for marketing and public relations and frequently publications.
- Development or advancement offices, charged with the primary goal of raising funds through such activities as membership, grants writing, and fundraising campaigns.
- Facilities and grounds, maintaining all aspects of the museum site.
- Security personnel, responsible for human safety as well as disaster planning and mitigation.
- Librarian and/or archivist, organizing and maintaining scholarly materials and archival collections.
- Adjunct business personnel, such as museum shops and food service, all designed to add earned revenue to the financial mix.

In addition to the above, museums are employing greater use of technology in all of their functions. Information and

technology specialists are essential to maintain technology equipment and connections and to advise and develop many new tools and learning applications. Many museums are experimenting with handheld devices, powered by wireless technology, as educational aids and visitor guides. Interactive computers, videos, and large-screen theaters also require major growth and specialty within a museum’s technical staff.

Most American museums are highly professionalized. Access to professional standards is widely available through the many associations that serve museums and through numerous publications, conferences, and workshops. Since 1970, the AAM has set and promoted standards and best practices through its Accreditation Program. Museum associations, such as the American Association for State and Local History, have also developed standards that are specifically applicable to small museums, including those that are managed by small paid staff or are fully operated by volunteers. Other specialized associations, such as the Association of Zoos and Aquariums offer their own, more highly focused, accreditation programs. These programs reflect the changes over the years in traditional museum practices, expanding to embrace evolving roles and issues in collecting, educating, and serving the public. They include an emphasis on museum ethics and address such emerging issues as collections related to Nazi-era provenance and Native American repatriation.

The AAM is the overarching professional association serving the nation’s museums. However, a number of affiliate organizations, who work collaboratively with AAM in professional deliberations, exist to meet the specialized needs of the diverse museum types. These affiliates include:

- American Association of Museum Volunteers.
- American Association for State and Local History.
- American Federation of the Arts.
- The American Institute for Conservation of Historic and Artistic Works.
- American Public Gardens Association.
- American Zoo and Aquarium Association.
- Association for Living History, Farm, and Agricultural Museums.
- Association of African American Museums.
- Association of Art Museum Directors.
- Association of Children’s Museums.
- Association of College and University Museums and Galleries.
- Association of Railway Museums, Inc.
- Association of Science Museum Directors.
- Association of Science-Technology Centers Incorporated.
- College Art Association.
- Council for Museum Anthropology.
- Council of American Jewish Museums.

- International Association of Museum Facility Administrators.
- International Museum Theatre Alliance.
- Museum Computer Network.
- Museum Store Association.
- Museum Trustee Association.
- National Science Collections Alliance.

In addition to these associations, museums are also served by six regional associations and a number of professional interest committees.

Museums also have representation at the federal government level. The IMLS, established by the Museum and Library Services Act of 1996 and its subsequent reauthorization, is the federal agency with primary responsibility for government funding in support of both museums and libraries. The Act authorizes the agency to undertake the following leadership roles:

- To encourage and support museums in carrying out their public service roles of connecting the whole of society to cultural, artistic, historic, natural, and scientific understandings that constitute our heritage.
- To encourage and support museums in carrying out their educational role, as core providers of learning and in conjunction with schools, families, and communities.
- To encourage leadership, innovation, and applications of the most current technologies and practices to enhance museum services.
- To assist, encourage, and support museums in carrying out their stewardship responsibilities to achieve the highest standards in conservation and care of the cultural, historic, natural, and scientific heritage of the United States to benefit future generations.
- To assist, encourage, and support museums in achieving the highest standards of management and service to the public, and to ease the financial burden borne by museums as a result of their increasing use by the public.
- To support resource sharing and partnerships among museums, libraries, schools, and other community organizations.^[7]

Each year, Congress and the Executive Office determine the amount of support allocated to these purposes within the federal budget. In 2007, the support for museums was approximately \$32 million.

Additional grant support for museum programs and services may also come through the National Science Foundation, the National Endowment for the Arts, the National Endowment for the Humanities, and the National Institutes for Health. Occasional funding is sometimes related to special initiatives of other federal agencies as well.

STEWARDSHIP OF COLLECTIONS

The core activities of most museums are found within their mission statements and are generally identified as collecting, preserving, researching, exhibiting, and interpreting. Each activity is undertaken as part of the public trust, which assigns the care and conservation of collections to the museum in return for learning more about these collections and their role and relationship to the human experience.

Collections are at the core of the museum experience and are often cited as what differentiates the museum experience from other similar experiences. Museums offer the opportunity to learn from authentic objects. Museum collections have had many sources. They may have been amassed by a private collector, by such an institution as the Catholic Church and its leadership, through the spoils of war, by a civic enterprise seeking to preserve its history, a university, a scientific expedition, or perhaps an informal association bound to a common preservation goal. Many large urban museums set on a course of assembling great collections as a source of civic pride. Many small institutions exist to share the quirky interests of a single, dedicated collector. Scientific and natural history collections have often been acquired by subject specialists interested in studying specific species or scientific phenomenon. Whatever the source, collections become a centerpiece of museum activity and require significant care and organization.

Frequently, as much as 80–90% of a museum's collection is not on public view at any given time. Stored collections must be carefully housed in conditions that provide appropriate temperature and humidity controls. Further, they must be kept safe from pest damage or other environmental factors that can erode their physical integrity and must be kept secure from theft. They must be protected from light as well, and often kept in mini environments designed specifically to preserve their unique materials and constructions. Providing such a safe environment and proper care is a fundamental responsibility of all museums. It is, however, very expensive and often requires highly skilled personnel.

The best of museums do provide such adequate care, but a recent survey undertaken by Heritage Preservation and funded by the IMLS, found extensive risk to the nation's collections, largely the result of inadequate funding. The report, known as the Heritage Health Index,^[8] states that over 4.8 billion artifacts are held in trust by more than 30,000 archives, historical societies, libraries, museums, scientific research collections, and archaeological repositories across the United States. Among the artifacts described as at risk are 4.7 million works of art; 13.5 million historic artifacts, such as flags, quilts, pottery, and Presidential memorabilia; 153 million photographs; 189 million natural science specimens, and as many as 270 million rare and unique books, periodicals,

and scrapbooks. Clearly, the care of collections, considered an essential responsibility of all of those institutions charged with preserving our heritage, is a massive undertaking.

Environmental controls, security, and disaster planning are needed to preserve collections. Also necessary, and frequently part of the museum's activities, are conservation practices that can repair and stabilize collections. The conservation of the enormous American flag at the National Museum of American History of the Smithsonian Institution drew national attention to the art of conservation. Conservation practices are always critical following such natural disasters as the Hurricane Katrina and many lesser but highly damaging events such as fires, floods, leaks, and insect damage. These efforts are a much underfunded aspect of many museums' essential work.

The acquisition and disposal of collections is generally governed by a Trustee-approved collections' plan that adheres to profession-wide policies. Deaccessioning policies, governing the sale of collections, have become increasingly controversial. Most museum associations have policies requiring that proceeds from such sales be used solely to support future acquisitions or serious conservation needs. Recently, some museums have challenged these restrictions, citing the need to use deaccessioning revenue to relieve severe financial stress. The topic is under review by several associations.

CURRENT TRENDS IN MUSEUMS

The late 1990s and early twenty-first century may be described as an era of accountability, particularly among government agencies and the foundation world. The focus on the tools of accountability, such as benchmarks, standards, and performance indicators, has had a profound impact on the nation's nonprofit organizations. The new and sweeping interest in quantitative and qualitative measures of success are leading to a new discipline within museum practice, that of audience research and evaluation.

The tightening of funding at all levels, including government sources and private foundations, has increased the scrutiny over the uses and impacts of such funding. Reporting requirements have changed. Emphasis has shifted from a reporting of project "outputs"—such as, the number of people served, lists of programs and events, descriptions of exhibits, types of activities—to "outcomes"—evidence of how these activities have benefited audiences and communities.

In 1993, the Government Performance and Results Act^[9] required that all federal funding agencies begin to gather objective evidence of the public good accomplished through such funding. Similar patterns and interest are now common among private foundations that support the work of nonprofit institutions of all kinds. Museums

and other cultural institutions have had to create and apply new measurements to their work, to capture both the quantitative and the qualitative impact of their programs and exhibits. Research and evaluation in museums is now receiving strong interest, both to meet the needs of these funding sources, as well as to provide essential feedback to museum practitioners.

The increased interest in obtaining evidence of impact is presently leading to consistent use of such techniques as audience surveys, focus groups, online questionnaires, and on-site interviews. Museums are hiring consultants and new staff to conduct evaluations of exhibits and programs at all stages of development, testing concepts before they are fully developed, trying out new exhibit models, and undertaking extensive summative evaluations to learn from each experience. The audience voice has never been so keenly sought in the history of American museums.

The accountability standards are just one aspect of a current museum trend to look toward the for-profit world for business models. Just as museum directors are frequently coming from the business world, boards of directors are exploring how new management techniques might apply to the operation of museums. The early years of this new century are filled with apprehension about the fiscal stability of many not-for-profit institutions, including museums. This concern emerges from changes in philanthropy and ongoing debates about the role of government in funding America's cultural organizations. Museums in most European countries, and indeed in many nations, enjoy much stronger, centralized support for their museums. The history of this country, however, and its support of entrepreneurship and private enterprise have created a much different model. America's museums are deeply engaged at this time in considering how best to achieve sustainability into the future. As in the past, much of the support for these institutions comes from individuals in the private sector. Competition for such dollars runs high, and museum boards and administration continue to explore new models consistent with the social and economic changes around them.

One such exploration has been in building closer and more direct relationships between museums and their publics. The enhanced role of audience feedback noted in the trend toward audience evaluation and research is also a significant factor in creating active communication between museums and their publics. The expectation that museums will serve broad public needs continues to expand. The last three decades have witnessed a growing trend for museums to shift their primary activity from the internal functions of collections care and exhibit development to an external interest in putting museum assets to work for the public good.

The image of a museum as a center for debate and discussion, controversy and convening is quite a different image from the museum as a treasure house of beautiful objects. However, the contemporary world of museums

and museum associations is advocating for a stronger public role for their institutions. The enormous collections of museums have the capacity to connect to current public issues in numerous ways. Children's museums, seen as trusted environments for young children and their parents, are using their popularity to address issues of concern to American families. Science museums are exploring such critical issues as global warming and other assaults on the environment, using the visual impact of their collections and trust in their scholarship to encourage their visitors to take action. Zoos and aquariums have long understood the public's affection for animals, dolphins, whales, and many kinds of living creatures. This understanding allows these institutions to use this positive response as a springboard to lessons in conservation. History museums, likewise, recognize the opportunity to present historic events that strongly echo current issues to enable visitors to link the lessons of the past to contemporary concerns.

Other forms of creating social value are also more commonplace in today's museums. In recent years many science-based institutions have created programs for underserved audiences. Science museums, for example, seeking to overcome gender bias have added numerous programs to attract girls to careers in science. Youth and teens have been given new voice in museum settings through programs focusing on building self esteem and social skills. Museums of all disciplines have showcased the achievements of diverse nationalities and races, serving as a catalyst for tolerance and cultural understanding. Following the events of September 11, 2001, for example, museums mounted exhibitions on Islamic art, science, and religion to present a more enlightened view of Islamic culture than what many Americans held. The rise of ethnically specific museums, such as African American and Native American museums, reflects the need to hear the

silent voices of the nation's past and celebrate the contributions of these societies and groups to American life. Recent years have witnessed the development of gay–lesbian–transsexual museums as well, also noting the degree to which American museums reflect and respond to current social concerns. Following challenges to the teaching of evolution, for example, some religious groups developed biblical museums to provide alternative points of view.

The dynamic history and development of America's museums, their breadth of collections and scholarly expertise, their educational impact and their deeper integration into the nation's communities are all challenging old images of stuffiness or pretension or exclusivity. These institutions are evolving with society and the idea of the American museum as a public forum is clearly a growing phenomenon.

Universal Decimal Classification (UDC)

I. C. McIlwaine

University College London, School of Library, Archive and Information Studies, London, U.K.

Abstract

This entry outlines the history, application, and nature of the Universal Decimal Classification (UDC). It explains its structure, management, revision, and the many changes that have taken place since the Task Force for UDC Development reported in 1990, and the UDC Consortium was formed. This led to the creation of the machine-readable database, or Master Reference File (MRF), consisting of some 66,000 terms, which forms the basis of all published editions and is revised and updated annually. Revision procedures and applications in an online environment are noted and the potential for future development discussed.

INTRODUCTION

The Universal Decimal Classification (UDC) is one of the major general classification schemes available for the organization of information. In many ways, it was the forerunner of later developments since, although it is based on the Dewey Decimal Classification (DDC), from the outset it included a number of auxiliary tables for the expression of recurring concepts, such as forms, languages, places, dates, the majority of which were not incorporated into the DDC parent scheme until well into the twentieth century. It is translated into a number of different languages, issued in a range of sizes and formats and now is controlled at the UDC headquarters in The Hague. An outline of the history, content, application, and potential together with the management that controls it is provided below.

HISTORY

The UDC has its origins in the project conceived by two Belgian lawyers, Paul Otlet and Henri La Fontaine at the end of the nineteenth century. They embarked on an ambitious enterprise to create a comprehensive listing of everything that had been written since the invention of printing, a *Répertoire bibliographique universel*. They decided to organize this information systematically in a vast card index and therefore sought an appropriate method for the arrangement. They were attracted to Dewey's *Decimal Classification* which, in 1895, had recently reached its fifth edition, so they entered into an agreement with Dewey to use his classification, with certain clearly defined modifications and expansions. At that time the scheme had only a few thousand subdivisions but its notation had great potential for universal usage because of the wider application of Arabic numerals than any other notational system. Otlet and La Fontaine expanded Dewey's scheme to suit their requirements and added a number of synthetic devices and

auxiliary tables which in due course turned the enumerative structure of the original into the much more flexible and detailed *Universal Decimal Classification*. The first edition of this expansion was published between 1905 and 1907 as *Manuel du Répertoire bibliographique universel*.^[1] It consisted of some 33,000 subdivisions and had an index of ca. 38,000 entries.

It became widely used in Europe in a range of different libraries, but World War I and the resultant shortage of funds led to the abandonment of the major bibliographical endeavor. The classification, however, survived and a much expanded second edition in French, now entitled *Classification décimale universelle*,^[2] was published in four volumes between 1927 and 1934. This second edition, together with later expansions and additions was used as the basis of all future editions for many years. Work began on editions in German and in English in the early 1930s, but again war interrupted work and the German edition was not completed until 1953^[3] and the full English edition was never completed.

The originators set up an organization to take responsibility for their work and to publish the accompanying classification, the Institut International de Bibliographie (IIB) also known as the Brussels Institute, after its original location. In 1931 the organization's name was changed to the International Institute of Documentation (IID) and as the result of increasing Dutch influence, largely emanating from Frits Donker Duyvis who had been an active participant in work on the scheme throughout the 1920s, its headquarters was moved to Deventer in the Netherlands and in 1937 it was moved once again to The Hague and its name was changed yet again, to the Fédération Internationale de Documentation (FID). Donker Duyvis's control of the scheme became absolute after the outbreak of World War II, and the deaths of La Fontaine in 1943 and of Otlet in 1944.^[4]

Editions of varying fullness have been published throughout the whole history of the scheme and by the

1980s it had been published in many languages and formats. The full edition consisted of over 200,000 classes at this date and it was supported by the worldwide network of FID's membership which consisted of around 100 countries. It has been calculated that it is used in approximately 111 countries^[5] and is available in some 38 different languages. It is frequently thought that its use is principally by specialized and in particular scientific and technical institutions. This is certainly true in the English-speaking world, and to a certain extent in Russia and the former members of the Soviet Union where its use was obligatory in such institutions. But it is widely used in libraries of all types in Spanish-speaking countries, in Portugal, and in many countries of Eastern Europe, ranging from children's libraries to large public and university libraries.

Historically, it was developed to three different levels, the full edition, medium editions (which became particularly popular from the 1970s onwards, thanks partly to the impetus from a three-language edition in French, German, and English envisaged as part of the celebrations for the centenary of Dewey's *Decimal Classification* in 1976) and abridged editions. It was also published in "special subject editions," with the major discipline(s) given the full expansion while other parts of the scheme which were the "fringe topics" to the principal interest but were needed for the organization of a specialist collection were outlined in an abbreviated form. Such editions include the *ABC Abridged Building Classification*^[6] and the *Universal Decimal Classification for Polar Libraries*.^[7] The most up-to-date such version is the *Global Forest Decimal Classification*^[8] which in 2006 is being revised and converted into an online version.^[9]

For many years, until the 1990s, the maintenance of the classification was undertaken in The Hague by the editor. This was originally under the supervision of Donker Duyvis and latterly in the charge of Geoffrey Lloyd and his staff together with the Secretary General of FID and a Central Classification Committee. This Committee was made up of representatives of the various language editions of the classification, together with representatives from the national committees responsible locally for the scheme. All changes had to be approved by this body and were circulated for approval prior to implementation. There was also at that time what was known as a "starvation policy" whereby no number could be reused with a different meaning for a period of 10 years. This revision method was an extremely slow and time-consuming exercise, especially the requirement to gain the approval of all the national committees prior to implementation. By the end of the 1980s FID found it was no longer in a position to maintain the classification at the level of development achieved in the past and that it was becoming both too expensive and too outdated in parts to be a manageable undertaking for the organization.^[10] It set up an international Task Force to investigate the viability of the classification and to recommend a policy for the future.^[11]

This body reported in 1990 and recommended among other improvements, the setting up of a Consortium of publishers to manage the classification and the creation of a machine-readable Master File of a maintainable size, approximately the size of that which had previously been known as a Medium Edition (ca. 60,000 + entries). This Consortium is known as the UDC Consortium (UDCC) and is managed by an Executive Committee, together with an Editor-in-chief and an Editorial Board, set up in 1994, who take care of the development of the classification. The "ten-year starvation rule" was also abolished at this time, permitting greater flexibility and the ability to incorporate new expansions and revisions in their logical place more speedily. The headquarters remain in the Koninklijke Bibliotheek in The Hague, and until its demise in 2000 FID was a member of the Consortium. Other members are the publishers of major language editions, such as English, French, Spanish, and Russian. Editions in other languages are produced by national publishers under license in a variety of formats and sizes. The office in The Hague is managed by the UDC Director who is responsible for issuing licenses, organizing subscriptions, and the day-to-day running of the business.

The machine-readable master file, known as the Master Reference File (MRF) is maintained in The Hague and is updated annually on January 1st, after the publication of the annual *Extensions and corrections to the UDC* in the preceding November. The original version of the Master File was based on the English Medium Edition of the Classification (BS 1000M: 1985) together with subsequent revisions and amendments up to 1992 as that material was already available in a machine-readable format. Most editions of the classification published since 1992 are the size of the MRF, approximately 66,000 entries in "standard" editions, or smaller editions, some as abbreviated as 4000 entries. It is issued in a range of different formats such as on CD-ROM or online as in the British Standards Institution's UDC Online, as well as in hard copy. The MRF is the authorized text and any developments that exceed its content are not authorized by the UDCC. The MRF exists in English only, but there is scope for expansion to include a range of other languages and proposals for a multilingual edition have been made. There are editions in French, Spanish, and Czech of similar size to the English master text which could form the basis of such an undertaking, but many published editions of the scheme are based on different stages of development and revision depending on the year when the translation began, and this creates obvious editorial problems for coordination.

STRUCTURE OF THE CLASSIFICATION

The outline of the main classes corresponds broadly to its parent, with the exception of class 4 which was vacated in the 1960s and has not been used since that date. But unlike

the original, there is no three figure base and each number is treated as if it were a decimal:

- 0 Generalities (including computer science, management)
- 1 Philosophy. Psychology
- 2 Religion. Theology
- 3 Social sciences (including gender studies, demography, sociology, politics, economics, law, public administration, and education)
- 4 Vacant
- 5 Mathematics and natural sciences (including environmental studies)
- 6 Applied sciences (including biotechnology, medicine, agriculture, transport, and technologies)
- 7 Fine arts. Applied arts. Entertainment. Games. Sport
- 8 Language. Linguistics. Literature (including philology)
- 9 Archaeology. Geography. Biography. History

NOTATION

In addition to its prime function of mechanizing the order, the UDC notation aims at expressiveness. Frequently the addition of a digit symbolizes a subdivision on a hierarchical basis:

597/599	Vertebrata
599	Mammalia. Mammals
599.8	Primates
599.88	Hylobatidae and Pongidae. Anthropoid apes
599.883	Pongidae
599.883.1	Orang utan
599.883.4	Chimpanzees
599.883.6	Gorilla

The notation makes two distinct uses of the numerals that are available; firstly, they are used as main numbers 1–9, expanded as required, and secondly as auxiliary numbers. The latter are numbers added to the main numbers to express additional facets of a subject, such as physical forms, geographic areas, chronological subdivisions, commonly recurring properties, etc., each with a distinct facet indicator. Each digit should be regarded as a decimal fraction, less than unity. For ease of reading a point, which has no mathematical significance, is introduced and a long number broken up, normally after every third digit:

6	Applied sciences
62	Engineering
622	Mining
622.2	Mining operations
622.23	Excavation
622.233	Drilling for blasting
622.233.4	Hammer drills and drilling

AUXILIARY TABLES

The auxiliary tables are of two kinds, common auxiliaries which express generally recurrent characteristics and special auxiliaries which denote locally recurrent characteristics. The common auxiliary subdivisions consist of numeric tables together with certain linking symbols used to join any concept in the main tables to any other. Each table has a distinctive piece of notation:

- 1a Co-ordination. Extension
+ , /
- 1b Relation. Subgrouping. Order fixing
:, [. . .], ::
- 1c Language
= . . .
- 1d Form
(0/09)
- 1e Place
(1/9)
- 1f Race, ethnic grouping and nationality
(= . . .)
- 1g Time
“ . . . ”
- 1h Subject specification by notations from non-UDC sources, e.g., A/Z
- 1k General characteristics
 - 02 Properties
 - 03 Materials
 - 04 Relations, Processes, and Operations
 - 05 Persons

In addition to these commonly applicable auxiliaries constantly recurring concepts within a limited subject field may be expressed by the use of special auxiliaries. Unlike the common auxiliaries the same notation may be used with a different meaning in the special auxiliaries occurring in different parts of the main tables. Three kinds of notation are used in special auxiliary tables: the hyphen series -1/-9 [but not -0 which is used for the common auxiliaries of general characteristics (Table 1k)] employed principally for an analytical or differentiative function, e.g., 82-1/-9 to denote literary form, etc.; the point-nought series, covering aspect studies, specialized activities, and operations, etc., e.g., in class 7 to denote styles and specialized principles, techniques, etc. in the Arts; and the apostrophe series which are usually more specific and are often synthetic in function, e.g., in 547—Organic Chemistry for chemical compounds.

Special auxiliaries may be used both to amplify the common auxiliaries, e.g., in the Area Table (1e) to express such concepts as the points of the compass:

(1-11)	East. Eastern
(4-11)	Eastern Europe
(44-11)	Eastern France
(443.61-11)	Eastern Paris

and to express particular concepts recurring throughout a single discipline or group of disciplines

7.079	Arts festivals
791.65.079	Film festivals
82:7.079	Literature festivals

Full details of the content and application of the main tables and the auxiliaries are set out in the introduction to the classification and in *The Universal Decimal Classification: A Guide to its Use* published by the UDCC.^[12]

THEORETICAL BASIS

Unlike its contemporaries at the end of the nineteenth century, the UDC incorporated a number of devices to make it more flexible and better to provide for the detailed specification essential for the bibliographic undertaking for which it was originally planned. It was the first truly analytico-synthetic classification, enabling any one concept to be linked notationally to another. In this way it foreshadowed the fully faceted schemes developed originally by Ranganathan some 35 years later, and followed especially by the Classification Research Group in the United Kingdom for the development of special classifications and indexing systems such as PRECIS in the years following World War II. It permits synthesis in several ways. Classes that have been developed or revised since the 1980s are all fully faceted. Examples include Class 2—Religion, Class 8—Literature and Language, and Class 93/94—History. This is implemented through the use of the colon and the other connecting symbols outlined above to join together two or more concepts. This facility makes it possible to express compound topics and to develop the classification to accommodate new topics which frequently have their roots in previously existing disciplines. Classes that have been developed by means of this device include 502/504—Environmental Science and 60—Biotechnology, where much of the detail is gained through the use of the colon, e.g.:

502.3.272:531.62	Energy conservation
502.3:551.510.534:502.12	Ozone layer depletion
602.6:599.323MUS	Creation of transgenic mice
602.643:54-126	Polymers as vectors
602.72:612.646:602.9	Cloning of human embryos for stem cell research

The array of common auxiliaries also makes for considerable flexibility, as does the facility for intercalation of those which have a clearly marked beginning and end, such as the notations in Tables 1e and 1f for Area and

Time, respectively. Intercalation provides the means of changing the citation order to suit individual needs. Class 34—Law provides an example of this, where the main schedule for Law is divided first by legal topic, but it may be found more convenient to have an arrangement of Legal system—legal subject, e.g.:

347(410.5).23 Scotland—Property law
rather than
347.23(410.5) Property law—Scotland

This flexibility has been greatly enhanced by the development of Table 1k, especially the concepts listed at -02—Common auxiliaries of Properties and -04—Common auxiliaries of Relations, Processes, and Operations.

All revisions which have taken place since the 1980s have been fully faceted and have a notation that reflects the hierarchical position of each concept, to aid machine-searching, so that it is possible to search up and down a hierarchy by truncating or extending the notation. Class 2—Religion provides an excellent example of this approach. This classification was introduced in 2000 and is the first attempt by a general scheme of classification to present an unbiased approach to the discipline.^[13] The class is arranged so that each religion is listed and accompanied by a series of auxiliary tables enabling the enumeration of appropriate concepts. The classification therefore provides a listing of faiths and the notation used for listing those faiths is simply an ordering device, and in no way implies any subordination of one to another, because of the problem of enumerating so large a number. The religions are arranged according to their historical origin, beginning with prehistoric and primitive religions. The “big five” faiths, Hinduism, Buddhism, Judaism, Christianity, and Islam are all allocated a two-digit number, the remainder in some cases have longer notations. Moving on from the enumeration of the various faiths and religions, the principal facets (in inverted order, following the principle adopted in all recent revisions) are as follows:

Religion	
(Theory and philosophy)	Religious concepts and ideas
(Evidences of religion)	Sacred books. Scriptures
(Agents)	Persons in the subject
(Operations)	Social and ritual practice and observance
(Processes)	Development, decline, interfaith relations
(Parts)	Religious organizations, associations, orders, sects, and movements
(Kinds)	Religions by various characteristics e.g., Orthodox, Liberal, monotheistic
(Entities, Systems)	Specific religions and faiths

CITATION ORDER

There is no official introduction to UDC editions and the many editions of the classification usually include their own introductions, frequently copied (with or without permission) from other editions. Instructions on usage appear in the various guides issued in a range of languages, the most recent being translations of *The UDC: A Guide to its Use*^[14] but notable for its clarity and authority is Jack Mills' Guide of 1963 authorized by the British Standards Institution (BS1000C: 1963).^[15] A fixed, obligatory citation order raises problems with so flexible and adaptable a classification. International exchange of bibliographic information requires a standard order but this can conflict with maximum expressiveness and the flexibility of the scheme appeals to many of its users who can adapt it to suit their own circumstances. Nowhere is there laid down a standard, compulsory order, but the MRF provides instructions on citation order in a number of places, particularly in the instructions for the application of the Common Auxiliaries, especially those in Table 1k the Common Auxiliaries of Properties, Materials, Relations, Processes and Operations, and Persons which may not be used independently or cited first in a compound notation. The current MRF is far from uniform in its recommendations in this matter but the default citation order, which follows the principle of inversion, works well in the majority of cases where there is no specialist requirement. As at present constituted, it would be exceedingly difficult to impose a rigid citation order and it is most unlikely that it would be followed by users who are accustomed to adapting the classification to their specialized requirements.^[16]

FILING ORDER

Unlike citation order, which depends to a certain extent upon the needs of individual circumstances, a fixed filing order is laid down for the arrangement of the various codes which represent concepts in the UDC. There is a fixed order for the filing of the various symbols so that a user should be able to anticipate the arrangement when consulting a UDC file.

The filing order in the UDC is based on the principle of proceeding from the general to the particular and is demonstrated below:

Symbol	Example
Independent auxiliaries	
= =112.2	German language (i.e., documents in German)
(0...) (0.035.22)	Microfilmed documents
(1/9) (430)	Germany
(=...) (=1.410)	British nationals
"..." "19"	Twentieth century
+	622.341.1+669.1
	Iron-ore mining and ferrous metallurgy

/	622.341.1/2	Mining of iron ores and manganese ores
Simple number		
	622.341.1	Iron-ore mining
Auxiliaries as suffixes		
:	622.341.1:338.124.4	Economic crises in iron-ore mining (<i>may be reversed</i> to form 338.124.4:622.341.1)
::	622.341.1::338.124.4	Economic crises in iron-ore mining (<i>may not be reversed</i>)
=	622.341.1=112.2	Documents in German about iron-ore mining
(0...)	622.341.1(0.035.22)	Microfilmed documents about iron-ore mining
(1/9)	622.341.1(430)	Iron-ore mining in Germany
(=...)	622.341.1(=411.21)	Iron-ore mining amongst Arabs
"..."	622.341.1"19"	Iron-ore mining in the twentieth century
*	622.341.1*Fe ₂ O ₃	Mining of red haematite (Fe ₂ O ₃)
A/Z	622.341.1GOE	Named iron ores: Goethite
-0	622.341.1-057.2	Manual workers in iron-ore mining
-1/-9	622.341.1-78	Protective devices and measures in iron-ore mining
.0	622.341.1.03	Geological character of iron-ore deposits
/	622.341.1'17	Wastes, residues from iron-ore mining
Next simple number		
	622.341.11	Mining magnetite-haematite ores

The filing order, by and large, follows the principles implicit in the standard citation order whereby within any given class mark subject concepts precede forms and place and time come last in the subject sequence. The use of the colon, however, may result in a more specific concept filing ahead of a general one, for example:

622.341.1:338.124.4 Economic crises in iron-ore mining
is much more specific than

622.341.1(0.035.22) Microfilmed documents about iron-ore mining

MAIN CLASSES

Although in broad outline, the classification resembles the DDC, there are many places where the two schemes diverge in detail. This is particularly true in classes 5 and 6 where different standard classifications for the sciences

have been followed. In the future, the detail of these classes may be altered to use the currently vacant class 4 to extend such disciplines as Medicine and its related sciences of Psychology, Biochemistry, etc. Class 0 has also been developed to incorporate Computer Science at 004 and Management at 005, since both are seen as being generally applicable. Both classes are fully faceted and contain concepts that will be needed throughout the classification, e.g.:

004.78:336.717	Online computing systems for banking transactions
005.521:330.133.1	Value analysis
005.912:656.874	Use of courier services

One development in 2006 which is noteworthy is collaboration of the UDC with its parent scheme. The DDC has been investigating the possibilities of adapting the new classification of class 2 for the creation of a less biased approach to religion. A project has been undertaken to map the UDC scheme onto the Dewey Class 200 and to convert the classification into a Dewey-like notation in order to improve the unbiased approach that Dewey has been attempting to achieve in recent editions. A pilot study mapping UDC 24—Buddhism to Dewey’s 194 class has been conducted and the conclusion has been reached that the more profitable approach is to use the UDC base with a revised DDC notation. Because the UDC is a fully faceted schedule and DDC’s auxiliaries differ considerably from those of UDC, mappings will be developed at the facet level for topics within the Religion schedule of both schemes. UDC has more detail than DDC and it is not intended to expand DDC to the same level of detail. The revised schedule for DDC is intended to be issued as an alternative in the first instance.^[17]

AUTOMATION AND THE UDC

The UDC was one of the earliest of the general schemes to be explored for its possibilities for mechanized retrieval. M. Rigby^[18] prepared a report in 1981 and subsequent research has resulted in the scheme’s application in a number of automated systems ranging from KWIC (Key Word in Context) indexes to the computerization of classified catalogs. The classification is particularly suited to machine searching. Its hierarchical structure facilitates searching up and down for more specific or more general concepts. The meaning of a number remains constant and therefore it is easy to retrieve concepts that have been expressed precoordinate in a postcoordinate manner.

A long-standing problem with the scheme has been the use of the colon to express relationships of all kinds, without distinction. Perrault,^[19] as long ago as 1968, published a “schema” of relators to clarify the ambiguities inherent in the use of the colon. This was a lengthy

schedule with an alphabetical notation identifying a large number of different types of relationship. It was circulated by FID in the previous year but was not received with much enthusiasm and was never incorporated into the structure of the classification. Another proposal along similar lines was made by Caless as the result of work at the VELA Seismic Information Analysis Center of the University of Michigan.^[20] This also, was never incorporated into the scheme. However, the introduction of Table 1k-04—Table of Common Relations, Processes, and Operations in 2003 has resulted in the ability to express 11 different phase relations, such as bias phase, association, dependence, complementarity, etc., thereby greatly improving expressiveness and addressing the problems identified half a century previously.

One of the earliest projects with machine-retrieval was Automatic Direct Access to information with Online UDC System (AUDACIOUS) undertaken by Freeman and Atherton in 1967–1968 at the American Institute of Physics.^[21] This was a command-driven, interactive system which used the nuclear science sections of the UDC schedules with English descriptions. It provided remote direct access to files containing 2330 items from Nuclear Science Abstracts which were indexed by UDC and was part of a larger project which provided machine-readable files of UDC, automatic typesetting, composition of UDC schedules, and a statistical evaluation of the classification as a retrieval tool. The resultant conclusions had considerable influence on future applications. Throughout the late 1960s and early 1970s a series of conferences was held to examine the possibilities of the UDC as a retrieval tool.^[22–24] The impetus faded, however, with the financial problems of FID during the 1980s and it was not until a decade later that much interest was demonstrated in the use of UDC in a networked environment. Buxton^[25] in 1990 examined the feasibility of using the scheme in these circumstances, drawing attention to examples of automated usage and also highlighting the shortcomings of the scheme for such application, such as the tendency to repeat the same concept in different parts of the schedule, due to the dependence of the classification on “aspect.” This is a problem that recent revisions have taken note of and continue to address and correct. There are many concepts scattered throughout the schedules, as in the following example of “alcohol”:

Practical laboratory chemistry	542.423	Heating by alcohol
Analytical chemistry	543.632.532	Hydroxyl groups, free alcohols
Organic chemistry	547.26	Saturated monohydric alcohols
Medicine	613.81	Alcoholic drinks
Engineering	62-631.4	Alcohol
Chemical technology	661.72	Alcohols and their derivatives
Industry	678.744.7	Polyvinyl alcohol

There are, however, bonuses to this apparent scattering, as if one wishes to contextualize a search and focus on browsing to improve precision, the aspect element of the classification is a considerable advantage, since it is possible, for example, to retrieve everything concerning medical aspects of alcohol and exclude all other contexts by simply using the 613.81 notation rather than searching on words. Recall is improved further in systems where it is possible to use words in combination with UDC numbers.

The advent of the Online Public Access Catalog (OPAC) presented opportunities for exploiting the facility for searching, browsing, and displaying classification data that the UDC offers, and which traditional classified catalogs had used to advantage for decades. By and large, this feature of the classification has not been realized. Where its potential has been implemented in an OPAC it is by libraries which purchased specially designed systems such as ETHICS at the Eidgenössischen Hochschule in Zurich^[26] and the MUSCAT system used by the Scott Polar Library in Cambridge (U.K.).^[27] For the UDC to be effectively applied in an OPAC it is essential to have an automated classification schedule, an authority file for the classification, and an interface which permits the display and browsing of hierarchies and provide both simple and postcoordinate search facilities that use both classmarks and natural language.

The use of classification on the Internet has resulted in a number of research projects such as DESIRE, NORDIC, SCORPION, and CORC, and these have demonstrated that classification can play a significant role in improving searchability. The full potential of library classification in general and of UDC in particular has yet to be realized. The classification is, however, used to provide quality information via certain services which attempt to create directories by analyzing and classifying resources intellectually and employ programs for the automatic harvesting and classification of resources. Automatic classification of Internet resources becomes all the more urgent as their growth makes any manual classification unmanageable. Services classified by UDC include SOSIG and NISS. SOSIG—Social Science Information Gateway (<http://sosig.ac.uk>) has over 50,000 social sciences Web pages stored in the database which is regularly updated. In 2006 it incorporated Law and was relaunched as INTUTE (<http://www.ukcle.ac.uk/directions/previous/issue4/sosig.html>). NISS—National Information on Software and Services) Information Gateway (<http://niss.ac.uk>) is a U.K. national information service for the education community which is part of HERO (Higher Education and Research Opportunities in the United Kingdom) (<http://www.hero.ac.uk>). Both services are based on very broad headings from UDC and on out-of-date versions of the scheme, though they may incorporate more recent amendments. This cannot be discerned as they do not display the UDC structure on the interface or UDC numbers in the metadata.^[28]

Automatic classification using UDC should ideally make provision for creating both simple and compound numbers, using vocabulary built up in an authority file. A more rigorous approach to defining the content of Web documents has been detected in Web sites which integrate UDC into their operation.^[29] The synthetic approach of UDC means that concepts are expressed by a notation that is built up during the process of classification, rather than appearing readymade in the schedules. Hence the necessity for an authority list which must be accompanied by an index to the scheme enhanced by natural language terms that may occur in a full-text database. This is not an easy task to create, and the majority of existing automatic classification systems tend to extract terms from the schedules and to limit their selection to simple numbers. Examples of services which have experimented with automatic classification include WWW Subject Tree of WAIS (Wide Area Information Server) Databases. This gateway is part of the Nordic WAIS/World Wide Web Project (http://www.ub2.lu.se/autpo_new/UDC.html).^[30]

Another project using UDC for automatic classification was GERHARD (German Harvest automated Retrieval and Directory (<http://www.gerhard.de/>) which was focused on the classifying and indexing of German Web pages. It integrated both searching and browsing facilities. The researchers used a trilingual version of UDC comprising 60,000 entries, and 15 different relations are possible. Each entry includes a UDC notation and a natural language description with synonyms in German, English, and French. The objective was to convert the classification to a lexicon that mapped classification entries to the codes in the scheme. Natural language expressions of the documents were matched with the UDC entries using linguistic classification. GERHARD demonstrates the advantages of having a classification as the backbone of the retrieval system. The number of documents assigned to a given category is clear, as is the number of documents in displayed subcategories. It is easy to move through the hierarchy of categories and the system is user-friendly. Until 2006, when it ceased to be available, it was the most sophisticated application of the UDC for the purpose of Internet resource discovery.

CONCLUSION

The UDC is a classification that is widely used in the non-English speaking world, both for the traditional purpose of arranging books on shelves and for application in more sophisticated retrieval systems. It has great potential for application in a networked world since it is possible to create a system that permits searching on each separate element in a classmark and to combine words and numbers for the purposes of searching. Recent revision work has concentrated on increasing the basis of facet analysis throughout the scheme and on eliminating places where

the same concept is repeated in a different context, in order to improve the structure for machine searching. The use of a sophisticated system such as this is very expensive and the full potential of UDC has yet to be realized in the modern environment.

University Archives

William J. Maher

Archives, University of Illinois at Urbana-Champaign, Urbana, Illinois, U.S.A.

Abstract

Universities, colleges, polytechnic institutes, arts academies, and other postsecondary institutions have established archival programs to hold and make accessible the documentary heritage of those institutions in order to protect individual and institutional rights and to provide a cultural context for understanding of the institution's past. University archives are managed by professional archivists following best practices of the archival field, but they are reflective of the distinctive history of the particular institution.

EMERGENCE AND DEVELOPMENT OF UNIVERSITY ARCHIVES

The post-World War II era's great expansion in higher education has supported an equally dramatic growth in the establishment and scope of university archival programs. After many years largely in the shadow of governmental archives and private historical societies, academic archives have finally come into their own, and many academic archivists have assumed leadership positions in the international community of archivists. Indeed, the archives now found in the world's universities, colleges, and other institutions of postsecondary education contain some of the most important materials for understanding culture and society. Over the same period, while historically a discipline separate from library and information science, archives have grown closer to library practices. Although manuscripts and special collections have been part of academic libraries for decades, they were often relegated to the periphery, and a typical approach was to apply item-level cataloging and subject-oriented description rather than archival methodology. During the more general broadening of librarianship's scope starting in the early 1990s, archivists in academic libraries have experienced a greater acceptance of their need for autonomy to follow archival methodology at the same time that archival approaches have shown their usefulness for expanding areas of library materials.

Advances in technology for both the control of information materials and the very materials themselves have enabled a convergence of library and archives practices for capturing, preserving, and making accessible diverse information resources. However, there are enduring characteristics of archives that differentiate archivists from librarians: 1) archival materials are treated as aggregates; 2) the materials are viewed as organic or naturally occurring as the result of administrative action rather than as synthetically and retrospectively created; and 3) their nature inherently varies greatly from institution to institution, thus making standardization difficult.^[1,2]

The variety among higher education archives renders generalizations difficult because, when examined closely, any generalized picture may not fit well with the characteristics of a given archives, its parent institution, or even the overall type of educational institution to which an archives belongs. Still an overview is enormously useful as an introduction, as a way of assessing relative practices, and as groundwork for the identification of norms for future development.

DEFINITIONS

Some definitions are needed to frame the discussion of the scope, contents, and functioning of university archives. For the purpose of this entry, archives may be defined as the organized noncurrent records of an institution, organization, family, or individual deemed to have enduring value and retained for administrative or research use. The purposes of archives include accountability, preservation of heritage, and services as a laboratory for educational programs. Archives also refers to the formal program that manages records of enduring value, the physical place occupied by the program, and to the materials held in such repositories. Additionally, in common professional parlance, "archives" is used to describe a wide variety of documentary forms from institutional and private sources, whether created formally as part of a systematic records system or as the result of private collecting of material based on its subject content.^[3]

Nevertheless, there is value in understanding the differences among three related categories of archival materials: traditional records created by official institutional transactions; privately generated or "personal archives;" and "manuscript collections"—materials synthetically collected and retained for their subject matter pertinence. The distinction of archives from manuscripts is a particularly relevant in regard to university archives because of the tendencies of academic libraries to focus on subject

matter pertinence and item-level control even when dealing with manuscripts. Although the methodologies and resources needed for archives, private papers, and manuscript collections vary, university archival programs frequently contain all three categories, because all three often have a bearing on the fundamental university archival responsibility of providing accountability and preserving heritage. However, to understand the core of university archives worldwide, it may be best to focus only on the basic institutional records program, along with that limited body of private papers bearing directly on the institution, such as faculty papers. In this context, the core would not include the unrelated “manuscript” gatherings that have become so popular in U.S. colleges and universities.^[4]

Equally important for this entry is a definition of “university.” University archives occur in all types of postsecondary educational institutions, whether they are polytechnic institutes, 2 or 4 year programs, graduate research universities, specialized professional colleges (such as law or medicine), or arts and music schools. Further diversity is introduced by the matter of sponsorship or affiliation: universities may be official organs of a governmental authority or privately supported by tuition funds and endowments. In addition, one particular type of private institution—the religiously affiliated—will also result in significant differences, depending on denominational or doctrinal connection and institutional mission (general education vs. training of clergy for religious service).

VARIABLES AFFECTING THE NATURE OF UNIVERSITY ARCHIVES

There are additional typologies which can have significant bearing on university archives’ holdings and user constituencies. For example, in a general research university with both graduate and undergraduate programs in the arts and sciences, the archives can serve as a research laboratory where undergraduate and graduate students in disciplines such as history, anthropology, and languages may exploit the university’s past as a means of learning how to do research or narrative writing. In a university that is predominately a professional school (e.g., law, medicine, or engineering), connecting students with the university’s past through archivally based assignments may be less possible, and the archives may find that a proportionately greater part of its users are the alumni and fund-raising offices. Schools of art, music, dance, and theatre are similar in many respects to the professional and technical schools, but they may place greater emphasis on non-textual records. At nonresidential 4-year undergraduate and 2-year “junior” colleges, the archives’ challenge may be to connect with the students when their time on campus is far more limited, necessitating a more active outreach

program so those archivists may engage their student clientele.

All of these variations can come together to have an important influence on what kinds of records and manuscripts are available to the archives. While certain core administrative records (e.g., catalogs, faculty minutes, executive officers’ reports, correspondence, and policy documents) will be fundamental to any kind of university, the variety and scope of faculty personal papers may be far greater in a general university with strong social science programs than in, for example, an engineering institute or music academy where the disciplines themselves are much less focused on textual studies and textual production. Of course, this is not to say that the papers of engineers and musicians are any less valuable; rather, documenting the careers of such faculty may be a greater archival challenge.

Two other environmental variables can have further significant effect on the nature of the university archives: country/national traditions and age of institution. Country of origin, national traditions, or other governmental mandates can dictate much of the character of a university. Beyond the clear effect that national public-records laws have on the archivist’s authority to control what does and does not come to the archives and on what is mandated for public access, national traditions can effect the character of universities and thus their archives. For example, a postcolonial public university in an African or South Asian country may well be focused on technical training, technological advancement, and the development of a national literature. In a European postcommunist country, traditions of centralized control may still persist, making it possible for its archivist to apply administrative mandates for the management of records. By contrast, in the United States, the fierce tradition of state-by-state independence and distrust of central government authority makes it difficult to develop consistent archival policies for the routine systematic transfer of records to university archives.

While there are a number of important universities well-known for their great age, e.g., Bologna, Paris, Oxford, and Harvard, the inescapable fact is that worldwide, the majority of institutions date from the twentieth century. Universities of significant antiquity face challenges in balancing attention to very old documents (with almost relic status) against modern items that by comparison to medieval papal bulls or princely commissions with wax seals can seem quite mundane. On the other hand, newer universities do have an opportunity to apply the most modern professional archival standards to their heritage but with the proximity of their own past and their urgent need to establish their authenticity, their relatively young age may lead such universities to discount their past so much that archives are at the bottom of their priority lists for financial and policy resources.

NATURE OF A UNIVERSITY ARCHIVES AND DOMAINS OF ARCHIVAL WORK

Recognizing the limits of generalizations, we can still define a university archives as a formally authorized and professionally managed program for the selection, accessioning, arrangement, description, preservation, and use of the official records, personal archives, and private manuscripts of enduring value for telling the story of the university, its programs, people, and place. An archives exists to support accountability and documentation of institutional and personal rights, and to enrich the university and its people by the preservation and presentation of its cultural heritage.

Professional management of the university archives consists of systematic practices in seven distinct archival domains:

Effective authorization of the archives by the parent institutions allows the program to ensure the retention, preservation, and utilization of archival holdings.

Authentication of documentary information through the analysis of its content and evidence obtained during the process of its accession or through a systematic records management program ensures the integrity of the archival record.

Appraisal of documents for their value as evidence and information on the basis of anticipated use in relation to the costs of description and retention ensures the selection of the smallest and best body of records.

Arrangement of information according to source and original order to sustain the integrity the documents had while in active use, following the related principles of *respect des fonds*, provenance, and sanctity of the original order guarantee that the archival holdings reflect their original meaning and relationships.

Description of documents, according to best practices and standards, via finding aids, guides, and inventories enables long-term access to their informational contents and ongoing administrative control of the holdings.

Preservation or physical protection ensures the future availability of documents in a safe environment and on physical media that will remain accessible, renewable, or convertible for the period of expected use.

Archivists promote and facilitate the use of documents to explain the past, provide guidance in the present, and accountability to the future.

In the three common understandings of the word “archives”—as documentary material, as a physical place, and as a program that manages these materials—it is the documentary content which has the greatest visibility to the program’s parent institution and constituencies. Archival material can come in all physical formats including

stone, cloth, parchment, paper, glass, plastics, and electronic media. Likewise, archival information can be recorded as words, numbers, codes, images, sounds, and moving images. To achieve its purpose, the university archives must be all-inclusive of physical media and recording structures.

HOLDINGS OF A UNIVERSITY ARCHIVES

Regardless of physical materials or record formats, an overarching typology of the holdings needed in a university archives consists of the following: official or office records (correspondence, reports, minutes, images, etc.) created by university officers and staff to complete their individual mandates; publications (documents produced by the institution in multiple print copies or via broadcast/posting on the Internet) whether of a bureaucratic, promotional, scientific, or cultural nature; and personal papers (material in all physical formats created and retained by individual students, faculty, and alumni reflecting their professional and private lives as members of the social community of the institution). Adequate documentation of the university requires attention to all three of these categories, although those archives maintained primarily for administrative purposes may emphasize official records and publications at the expense of the more personal, human, and diffuse picture that is drawn by personal papers.

Some professional literature has attempted to list the variety of specific records that should be part of a university archives.^[5] These inventories proceed on a hierarchical structural analysis mentioning such items as catalogs, graduation lists, policies and regulations, minutes, reports and correspondence of the board of control, chief executive officers, academic officers (provosts, rectors, and deans), faculty assemblies, and student affairs administration, and facilities managers. Such lists are useful points of reference, but a functional rather than structural analysis may provide a more strategically useful typology.^[6] True, one might end up identifying such a broad array of documentation for the archivist to manage that it may seem to offer little advantage over the more traditional structural and hierarchical model, but the functional approach is an efficient way to strategically sequence decisions centered on the context of the records. The functional analysis approach should help archivists at different types of institutions to de-emphasize some areas when they are not relevant to that type of institution. For example, at a 2-year or 4-year undergraduate college, the archivist might make the strategic decision to de-emphasize the function of the creation of new knowledge while an archivist at a general university with a strong research emphasis may make the strategic choice of de-emphasizing efforts to accessions of materials on primary- and secondary-school teacher training.

CORE UNIVERSITY FUNCTIONS TO BE DOCUMENTED

In general, the core functions of a university to consider in relation to a university archives are:

Establish and sustain functions are those legal and administrative activities that create and support the continued existence of the university. This area includes not just charters and legislative mandates, but also records of financial administration, fund-raising, property acquisition, physical plant planning and development, employment management, and institutional reporting.

Educate. While many universities have been particularly wily in taking on multiple personae, by definition their signature function is to educate students. Important documentation of this function may include course catalogs, syllabi, grade records, Web course sequences, and student notebooks, exams, and papers. Operating strategically, a university archives may elect to limit accessions for the educate function to just course descriptions and grade records, or if funded sufficiently, it might decide to document the learning process by capturing Web course content, class blogs, and student essays.

Creation of knowledge. Universities, especially those with postbaccalaureate programs put a great emphasis on having faculty and advanced students engaged in the discovery of new knowledge, the writing of scientific research studies, and the making and performance of cultural and artistic works. Inevitably, documentation of this function requires attention to the personal papers of faculty and sometimes students through materials such as laboratory notebooks, manuscript drafts, or audio, and video recordings of performances, but it also requires administrative office records on the management of research laboratories, research funding grants and contracts, performing arts facilities, and cultural and scientific museums.

Socialization. Whether one regards higher education as an authoritarian effort to restrain the excesses of post-adolescent youth or merely confine them until the hormones settle, the fact is that universities bring together large numbers of maturing individuals who quickly form social networks through educational and extracurricular activities. Not only is the place of the university in the former student's life very much defined by the socialization that occurs there, but the university itself is also defined by its student and faculty life. Socialization can be one of the most important educational functions of the university. By its very nature as a matter of intangible personal interactions, the socialization function is difficult to document. Clearly, personal papers, (such as diaries, scrapbooks, blogs, MySpace[®] sites, photo albums, and correspondence) will be essential for documentation of this function in any depth. Because such materials can be complicated to acquire, describe, and preserve, some university archives may choose to limit their work in this area to keeping only the official records and publications

pertaining to the institutional structures in which the socialization occurs, such as housing regulations, programs for intramural clubs and athletics, student newspapers, and organization Web sites, although broader coverage may provide for a very lively archival program of appeal to many extra-institutional researchers.

Public engagement. An enduring function of universities is the broad range of activities by which the institution interacts with the general populace as a whole. These activities include continuing education and extension programs whereby the knowledge of the university's specialized disciplines is distributed to the public as applied services and thus can range from agricultural information bulletins, medical services, and veterinary clinics to evening and distance-learning classes. Public engagement activities can also include music extension courses, art exhibitions, musical and dramatic performances, and public athletic events. The popularity of some of these activities can often mean that the university has great public visibility and that the archives receives many reference requests for historical information about these engagement programs. Thus, even though some such activities (e.g., "big time" intercollegiate athletics) at first might not seem to be central to the mission of higher education, failing to document them, even if only at the strategically limited level of maintaining a record set of event programs, will deprive the archives of an opportunity to connect with a nonspecialist public audience.

PROGRAMMATIC ACTIVITIES OF A UNIVERSITY ARCHIVES

A successful university archives is certainly more than a gathering of interesting and important historical records. It needs to incorporate a number of programmatic activities beyond those identified as the seven core domains noted above. Although not every archives can be deeply engaged in each, attention to a healthy mix is important. These programs can include oral history to capture the memories and character of members of the university community, and to fill-in gaps in the "written" record.^[7] Exhibits and other outreach programs, such as concerts, open houses, exhibitions, lectures, performances, history contests, media appearances, curricular presentations or instructional programs to the campus and community schools, publications, etc., are important for ensuring a steady flow of research users to the archives and to counteract the false impression that archives are merely dusty obscure documents of little relevance to today's public. Limited by the strictures of intellectual property law, digitization projects that result in Internet posting of historical documents of interest to the general public (e.g., genealogical information) can be an effective way of engaging the public in the archives' mission while also enhancing the university's reputation.^[8] Records and information management services, while related to the

core ability to document the university, can also be built as a supplemental program to extend beyond mere records disposition scheduling to include a full suite of records and information services (e.g., files management, scanning and imaging services, or vital records protection) and can help the archives expand its campus credibility while also improving the overall quality of university information.

CONSTITUENCIES SERVED

As evidenced by both the basic services to be offered and expanded programmatic activities, university archives have multiple and sometimes divergent constituencies. Its value to each will likely be rooted in different, if sometimes conflicting interests and expectations. For example, legal affairs and core administrative units rely on the archives to supply as complete a record as possible when the university needs to ensure that its actions are free of liabilities. Likewise, archives are needed in instances when the university must respond to claims against it. Alumni affairs and campus fund-raising offices may be most interested in the archives for historical narratives that enable them to connect the university's past with donors able to fund future developments. Faculty may look to the archives as a laboratory-like setting where their students can go to write research papers and speeches. Faculty also see archives as places where they can go to deposit collections of relevance to their own disciplines. For example, the archives may be asked by a faculty geographer to take on the records of a regional environmental action council that just succeeded in blocking a river damming project. Students are also an important, though highly divergent, archival constituency. On the one hand, the archives may be simply the place they go to learn how to use primary sources or to look up some historical fact in fulfillment of a class assignment. On the other hand, the archives may contain historical background on a club or activity they are seeking to join or revive. In less common, but not unheard of circumstances, students may come to the archives to absorb everything possible about the institution as they discover how compelling the past of something familiar can be. Similarly, for alumni, the archives is an ideal resource from which they can recreate those days of fond and intense memories. In addition, there are important external constituencies, including graduate students and scholars from other universities, local school groups, and news media writers and researchers. Understanding the different interests and needs of each constituency can be a challenge for the archivist, although the archivist should be careful not to cater so exclusively to any single constituency that it is defined primarily by that group. In fact, failing to cultivate multiple constituencies will jeopardize the success and even survival of the archives when resources become short, when administrations change, or when one particular constituency becomes alienated or weakened.

THE ARCHIVIST'S CHARACTERISTICS AND PROFESSIONAL BACKGROUND

As suggested by the breadth and depth of responsibilities, holdings, programs, and constituencies, the university archivist must perform quite a juggling act. University archival work requires strong written and oral communication skills, an interest in and patience for research, and a general tenacity. While such general management skills are absolutely essential, the archives clearly needs persons with training not only in historical methods but also in archival theory and methodology. Exact training options will vary from region to region and country to country, but they generally include course work and internships in archival studies presented in postbaccalaureate programs in history or library-science schools, or sometimes in national archival agencies. Regardless of preappointment training, it is important for the university archivist to be actively engaged in archival professional associations. On a regional, national, and international basis, such organizations offer continuing education opportunities, standards development, public policy advocacy, professional literature, and social networking through which university archivists can share problems and develop solutions.^{[9],[10]} Most importantly, they offer the challenge of a framework in which the university archivist examines his or her own problems and solutions in the context of practices and professional standards elsewhere, as well as in relation to archivists in other kinds of institutions such as governments, businesses, and religious bodies. At the same time, some of the general archival organizations often include subgroups just for university archives, such as the International Council on Archives' Section on University and Research Institution Archives (<http://www.library.uiuc.edu/ica-suv/>), the Society of American Archivists' College and University Archives Section (<http://www.archivists.org/saagroups/cnu/index.asp>), the Australian Society of Archivists' University Archives Special Interest Group (<http://www.archivists.org.au/structure.html#uni>), the Association of Canadian Archivists' University and College Archives Special Interest Section (http://archivists.ca/special_interest/university.aspx), or the Society of Archivists (U.K.) Archives for Education and Learning Group (<http://www.archives.org.uk/content.asp?id=148>). It is through such bodies that the profession has been defined and by which the advances of university archives will be measured.

Usability Testing of User Interfaces in Libraries

Sharon L. Walbridge

Libraries Washington State University, Pullman, Washington, U.S.A.

Abstract

As libraries face increasing competition in providing information, we must insure that our library systems are usable, effective, efficient, and perhaps even enticing. How do librarians know that systems give users what they need and want? One way is usability testing. Usability testing has been around the computer industry for at least a decade, but library use of the method is relatively new. It has been a common perception that library systems were designed for librarians. Even if the user was considered, it was from the perspective of librarians who worked with the user. Those perceptions were anecdotal, and librarians frequently disagreed with one another about user behavior and knowledge.

WHAT IS USABILITY TESTING?

Usability testing is the process of actually observing users working on a system or product, taking the information gained in that process, and making changes in the system under test, then testing again to see if the changes improved the system for users. It is not a formal research process, as a limited number of people are tested. It is not based on statistics, but on observation. What is proven again and again is that a small number of users, anywhere from three to eight, will yield 80% of the problems people will have with the system. In fact, in testing eight people, observers will begin to see patterns of problems after seeing four or five test participants.

WHY DO TESTING?

Rather than spending hours in committee meetings discussing effective system design, creating a system and then testing it will save time and energy. The order of buttons, how much information to include, whether a help function is usable, whether terminology is understandable, whether navigation paths are understood, where people will expect to find information, etc.—all of these aspects of systems can be evaluated via usability testing. The predictability of effective use of a library's online catalog or a website can be enhanced through such testing. Endless hours spent with programmers can be avoided. Results of usability testing can be used with system vendors to provide input on system upgrades. In fact, if system vendors do their own usability testing, their own design processes will be more efficient. Why should every library that buys a system have to go through time-consuming implementation to find errors that could have been caught early in the vendor's design process? As systems vendors offer more custom options, there are more choices

that need to be made. The best way to determine the effectiveness of choices is to ask the user.

Usability testing does not necessarily have to be a major time or effort commitment. It is better to test in small "chunks" rather than all-encompassing efforts. Common wisdom is to test small and often. For example, rather than test all aspects of the online catalog, focus on serials.

HOW DOES USABILITY TESTING DIFFER FROM BETA TESTING?

System vendors beta test to see if their systems work before delivery to customers. Beta testing differs from usability testing. While systems may work technically, they need to work effectively and efficiently and be understood by users. A system can be sophisticated in terms of having "bells and whistles," but users may not understand when to use those capabilities. Terminology and navigation may create inadvertent barriers to the usability of the system.

What are the various methods that can be used to test usability? In addition to formal usability testing, there are other ways to gain important input into user's perceptions and experience with the system. These include the following:

- Formal usability testing—actual users are observed using a system performing a list of predetermined tasks. Participants are asked to "think aloud," and observers record what is said and what is done.
- Card sort—used to gain information on the structure of a system or web page, index cards representing individual concepts are given to participants who arrange them in a structure that makes sense to them.
- Category membership—tests participants' understanding of various categories, including what they think should be in each category and what the category should be named.

- Focus group—small groups of people share their opinions and ideas on the system.
- Field study—users are observed in their natural environment as they carry out normal tasks.
- Automated testing—an automated form of usability testing that uses software to conduct test sessions and collect data.
- Walk-up kiosk—may be used in combination with automated testing, a booth with a computer allows users to interact with a system.
- Cognitive walkthrough—designers of the system try to predict users' actions by doing actual tasks themselves.
- Questionnaire—a set of questions is designed to collect responses and opinions of users regarding the system.
- Site usage log—server logs collect user transactions and movements and actions, and these are subsequently analyzed.
- Heuristic evaluation—a system interface is analyzed by evaluators using a set of usability principles.
- Interview—a semistructured conversation is held between individual users and information gatherers about the system being tested.
- Opinion poll—questions are asked of system users to get feedback on specific topics related to the system.

For more information on these various techniques, see <http://www.vancouver.wsu.edu/fac/campbell/usability/acrl>.

Usability testing can provide valuable feedback regarding on-line catalogs, web pages, and user guides—anything that is designed for users to find information, use information, etc. Signage, handouts, stack labels, stack arrangement, almost anything in the library that is designed to help users, can be evaluated and made more effective with usability testing.

DOING USABILITY TESTING

The following is a guide for libraries interested in doing usability testing. Start by doing some reading on the subject (<http://www.vancouver.wsu.edu/fac/diller/usability/usebib.htm>). There are several good books about usability testing and good websites. Jeffrey Rubins' *Handbook of Usability Testing* is a particularly good source for process and practical advice that can easily be adapted for library use.

PREPARE FOR TESTING

For an outline of formal usability test procedures, see <http://www.vancouver.wsu.edu/fac/campbell/usability/acrl>. For examples of all of the materials needed for usability testing, see <http://www.vancouver.wsu.edu/fac/diller/usability/contents.htm>.

Preparation for testing includes complying with institutional policies related to the use of human subjects, constructing a timetable, and formulating a purpose statement, problem statement, and task list.

While most universities have policies and procedures for testing human subjects, it may not be clear if usability testing is covered by these policies. The kind of human subject testing covered by institutional policy is usually physical or psychological. The university compliance office or institutional review board can determine if the library's testing is covered. Appropriate forms should be submitted for the project to the institutional review board or compliance officer.

A timetable is a guiding document and is essential in setting up tests and implementing them. The timetable specifies expectations, tasks, and all of the steps necessary to design and complete the testing. In libraries, it is often the case that those doing the testing have other responsibilities. The timetable lets everyone involved know what needs to be done and when tasks need to be completed.

The purpose statement is the key to a successful usability test. It answers the question of why testing is being carried out and helps to ensure that testing is directed to the processes for which user feedback is essential. For example, if the online catalog is being tested, the goal is to test people's ability to use that tool, not what is in the catalog, circulation policies, collection development effectiveness, etc.

The problems to be investigated relate to the purpose statement. Adherence to the purpose statement ensures that the problems relate specifically to the purpose of the project. The task list builds from the problem statements, as the problem statements build from the purpose statement, going from general to specific. Each step should help in refining the next, but care must be taken to make sure that each truly relates to and focuses on the next step.

The task list includes questions that comprise the actual test. Depending on the purpose and scope of the project, the test can vary from a few questions to many. Experts counsel that more focused tests and testing more often are more effective. Even if the test is fairly wide in scope, the test session should not exceed 1 hr, and 30 to 40 min is preferable. After a full hour, the participant and the observers will likely be tired.

How much to cover in any given usability test is an open issue. The number of questions to be included in an hour session can vary depending on the complexity of questions and tasks. Experience will likely indicate that shorter sessions with focused questions are better than longer sessions. This strategy will enable more effective smaller scope tests rather than comprehensive ones.

PREPARE MATERIALS

Materials to be prepared include introductory script, human subject consent forms, documents related to any

financial reimbursement, and data input sheets. Any equipment to be used in the test should be tested in advance to ensure a smooth test.

The introductory script is read to test participants to give them a uniform platform of understanding. It sets the tone for the session and helps to make the participant comfortable. The introduction should contain information on why the library is doing usability testing; the goals of the test; how results will be collected and used; and expression of gratitude for the persons' participation.

The human subject form needs to be explained to test participants and that institutional policy requires that they sign the form to indicate their consent. It is important that participants understand that the usability test is not an invasive one.

If a financial incentive is being offered, paperwork needs to be completed to make sure reimbursement occurs through the library or institution business office. Participants need to know that if their check is not received in a timely manner, they should check back with one of the observers.

Data input sheets are used to record whether or not the participant successfully completes the task; the time taken to complete the task; whether or not there were false starts; the steps taken to complete the task; and all comments made by the participant during the process of completing the task.

Equipment needed for the test will include, at minimum, a tape recorder, cassettes, a computer, and a clock. Participants need to know that they are not being tested, it is the system that is being tested. This message needs to be reemphasized to reassure the participant, especially if the person is having difficulty with the tasks during the session. Participants need to know that failure is as instructive as successful completion of tasks, because observers need to know the aspects of the system that work and those that do not work.

Self-confidence is important. Observers and test conductors will gain confidence as tasks are completed. Test participants will pick up observers' tension or lack of confidence. Careful and complete preparation increases confidence with the purposes and tasks of the test. Usability testing is serious business, but it can be fun for participants and observers.

TEST PARTICIPANTS

There are many ways to recruit volunteers for usability testing—flyers in the library, ads in campus or community newspapers, website notices, personal contacts at library service desks, etc. If demographics are important, it is advisable to use a screening questionnaire. For example, if a college, university, or public library is interested in testing the usability of its online catalog or website among its diverse community, each client segment can be tested

or a larger sample of people can be recruited. In a sample size of eight participants, an academic library could have three undergraduate students, three graduate students, and two faculty. Within that group, one would want a mix of males and females, traditional age students, and older students, etc. The screening questionnaire can help in choosing the volunteers. Questionnaires should identify status (undergraduate, graduate student, or faculty), age, sex, computer literacy, library use and knowledge, etc.

Librarians who have done usability testing report varying experiences in recruiting test participants. For some, it is easy to collect a pool of interested people, but for others, the process has been more difficult. Incentives help in either case. Whether the incentive is money, copy cards, gift certificates to the campus bookstore, etc., offering them lends a touch of credibility to the process. A little extra cash always appeals to students. Some universities may have policies against paying faculty for activities such as usability testing and faculty may participate as a symbol of support for the library.

In the case of universities, at least three communities of users—undergraduates, graduate students, and faculty—use the library and need to be tested. One of the obvious solutions is a two level interface—one for novices and one for the sophisticated user. It may be that this is not possible for system design or financial reasons. Regardless of whether there is one interface or two, the system still needs to be tested for usability. In the case of the website, there likely will be only one approach. In testing, one could have one group of test participants representing a demographic sampling of users, or one could have three groups of three representing the three primary user groups (undergraduates, graduate students, and faculty).

Pretesting the test questions helps to ensure that participants understand them. Are the tasks doable? Is the terminology easily understood? In a dynamic environment such as a website, are the test questions still appropriate or have changes been made that make the question no longer relevant?

Observers should actually take the test themselves so they have a sense of what steps will be necessary to complete the task. This testing will help observers follow test participants actions and judge whether or not their courses of action are legitimate, efficient, and effective. There may be several ways to get to an answer, but there is likely to be one "best way." Whether or not that is obvious to the user may be important.

In preparing for test sessions, tasks should be assigned to observers in advance. Who will meet the test participant and guide them to the test site? Who will read the introductory information? Who will ensure data sheets are in the room? Who will be responsible for seeing that the equipment is there in place and operating correctly? Who is activating the tape recorder? (If a video camera is being used, a third person should run it, but a tape recorder can be operated by one of the observers.) Who will give the

participant the summary general impression debriefing sheet? By deciding these questions in advance of the session, the test will run smoothly and appear to be more professional.

Some universities have invested in usability laboratories that enable them to use two video cameras and a separate observation room. OCLC Online Computer Library Center has three rooms—a control room, a test room, and a closed-circuit observation room. It is feasible for libraries to do a distinctly low-tech operation. A meeting room or office with a computer can be used as a bare-bones test facility. While it is beneficial to have at least one video camera trained on the screen, it is possible to use a cassette recorder to capture the test participants' comments. The audiocassette will enable observers to go back to check any comments that might have been missed or reconcile the observers notes on the comments. If an office or meeting room is used for testing, the environment needs to be uncluttered so that the atmosphere is conducive to concentration.

A clock should be available to test the time taken for each question comprising the test. The time taken is important, even if the tasks are completed successfully. If it takes more than a minute or two to answer straightforward questions in the test, the system needs to be examined in terms of efficiency.

Define success—there may be numerous ways to get the answer to a question. Is there one efficient and effective path or are there several? The answers need to be decided before administration of the test, so that the observers will agree as to whether or not a question has been successfully completed.

THE TEST SESSION

Meeting test participants and escorting them to the test facility will let users know their participation is valued. This time can be used to thank the person for volunteering and to begin to put the person at ease with small talk. In the test room, the participant should be introduced to observers and others in the room. The introductory script should be read by the designated observer, institutional policies regarding human subjects should be explained, and the participant should be asked to sign consent forms. Ask the person if there are any questions. Start the test.

During the test, the observers need to be alert and follow everything that is done and said. Once each task is completed, or the person has become hopelessly stuck and is ready to give up, observers should indicate that it is all right to move to the next task. If additional time is needed to complete recording of tasks and comments, ask the person to wait until the observers are caught up. Observers should ask the participant any questions they have about the process used or comments made before moving on to the next task.

One of the most difficult aspects of the process is having test participants verbalize what they are thinking and doing. This aspect of the test process is important, as it will offer clues and important information on how information is being interpreted, the logic of steps taken, and the understandability of terminology, content, etc. Recording ensures that nothing important is missed in the comments. It is beneficial to have the session videotaped, as the comments can relate more clearly to what is happening at the keyboard and on the screen.

The timing and content of observers' dialog with the participants is a difficult aspect of the process, as it is tempting to jump in to help, especially if the person appears to be lost. Experienced observers will gain confidence in their ability to talk with participants without unduly interfering, adding to a person's knowledge and therefore potentially "corrupting" the results. Periods of silence while the person struggles can be uncomfortable for all involved, but observers need to err to the side of caution to allow the test participant time to struggle through as they would in a real-life situation, where they needed information and were on their own with the library system.

AFTER THE TEST

Post-test activities consist of debriefing participants and observers and determining if changes need to be made in the system or if problems can be solved by instruction or online help.

The importance of debriefing after each test session cannot be overestimated. Debriefing the participant will give the person a chance to relax and to chat about the test experience. One of the most important aspects of this debriefing is the opportunity to do a little library instruction. Telling people what went wrong if they had problems with a particular task will enable them to immediately use the system more effectively. It is not unusual for participants to leave the test session with benefits in terms of things they did not know that they could immediately put into practice. This learning serves as another benefit of participation.

One of the elements involved in the debriefing can be a "general impression" questionnaire that gives participants the opportunity to make general comments about the system and to rate the system in general terms.

Debriefing the observers also is important. It is critical to do this debriefing in a timely fashion, preferably right after each session. Observers should go over the data input sheet and note any discrepancies in impressions of the results. Is there agreement on whether each task was completed successfully? What happened that was surprising or particularly interesting? As sessions proceed, are there common patterns or themes?

In analyzing test results, the goal is to decide what is needed to improve the problem areas. As soon as possible after a round of testing, data should be collected in terms of identification of problems areas—places where failures in completing tasks successfully occurred or the participants took too long in completing tasks or there were false starts, even if the tasks were accomplished successfully.

Given what was learned in the usability test, careful consideration should be made as to how the system can be improved. This may require some intensive thought and discussion, as the solutions to problems may not be obvious or simple. It is best not to put any constraints on thinking about how the changes can be implemented. Changes in the system are later steps in the process. Solutions may be two pronged—changes in system design as well as emphasis in library instruction. Who needs to be involved in making the changes? Is there a team that oversees changes to the website, or does a technical services unit (acquisitions, cataloging or serials processing) need to be approached to determine the feasibility of changes in the way information appears in the online catalog?

After initial evaluation of test results, the responsibility for making changes needs to be determined. Is the system customizable so that changes can be done in-house? If the answer is theoretically yes, are there resources to do it? If the answer is no, can the system vendor can be contacted directly, or is it necessary to go through a user group/enhancement process? Can the system be improved by education or instruction; can effectiveness be improved through by bibliographic instruction sessions? Would more online help in some form improve the system?

Retesting should be done every time changes are made in the system, whether those changes come about through usability testing or they are incorporated in a normal new release of software. If the changes have come about through usability testing, care should be taken to make sure the retest is similar to the initial test, to see whether the changes have actually helped the user in the identified problem areas. Ideally, the same questions should be asked again.

OUTCOMES

What Have Librarians Learned Through Usability Testing?

Users do not have a great deal of trouble navigating through systems. They become quickly frustrated and disenchanted with multiple layers.

Users do not understand normal library terms such as serial, monograph, volume, etc. There are a number of ways to deal with this problem, although none of them are guaranteed. Online glossaries, emphasis in library instruction sessions, use of standard terminology (not library jargon), and mouse-overs all may work to help the

situation. Users do not understand concepts such as the difference in content between the online catalog and full-text indexes. If they are asked to find a journal citation, more likely than not, they will look in the online catalog rather than full-text indexes. Again, the solution to this may be to attack the problem on as many fronts as possible, library instruction, mouse-overs, etc.

Users expect consistency. All of the students on a large university campus use the same catalog, and they may well use more than one library on campus. The library's website needs to contain the same information for each library on campus, preferably in the same place. If the libraries are decentralized, this can be problematic, but testing will prove that users expect consistency. As education becomes more and more interdisciplinary, the need for consistency will increase.

More and more library users access library systems from their dorm rooms, apartments, offices, computer labs, etc. Remote users should have as easy a time using the library's systems as do in-library users. Remote access impacts system design in relationship to images, etc. Even if systems are readily accessible from remote locations, different computer capabilities may exist for distance education students, disabled students, and others.

CONCLUSION

Librarians who have done usability testing quickly become advocates for the technique. Testing can yield quick results that can lead to increasing the effectiveness of the library's online catalog or the website. As outlined above, the process need not be expensive in terms of economics or effort. Although the first test experience may be more time consuming, the experience will make each successive test easier. Lessons learned in each process will bring efficiency to further testing. Usability testing is a rewarding way to bring accountability to critical library tools and to improve library operations.

User-Centered Design of Information Systems

Elaine G. Toms

Faculty of Management, Dalhousie University, Halifax, Nova Scotia, Canada

Abstract

User-centered design (UCD) emerged a couple of decades ago because people had difficulties in using systems. It is founded on the principle that users need to be involved in the design and development process for systems to be truly usable—efficient, effective, and satisfying. This entry provides an account of the background—the technological and social forces that affect the evolution of systems development, an explanation of the theoretical foundation on which UCD is build, and a description of a typical UCD process.

INTRODUCTION

Rationale, Definition, and Scope

User-Centered Design (UCD) was founded on the premise that knowledge of users and their participation in the way systems are designed is essential.^[1] User-centered design is a “multidisciplinary design approach based on the active involvement of users to improve the understanding of user and task requirements, and the interaction of user design and evaluation.”^[2] The emphasis is on “quality in use,” the ultimate goal of a UCD process. This is not merely about pandering to the wants of the consumer (i.e., developing what sells), as the marketplace is littered with market flops; it is about understanding and uncovering the current and prospective needs of the user, and developing solutions that do not “frustrate, cost, confuse, irritate, and kill us.”^[3] It is not to be confused with making products “user friendly,” a phrase that conjures up a rather pedantic notion of design, while at the same time making an implicit assessment about the “unfriendliness” of early systems.^[4] The UCD approach was intended to make systems that are “easy to buy, easy to unpack, easy to set up, easy to upgrade, easy to learn, easy to use, engaging, intuitive, and integrated.”^[5]

As a result of this human-machine mix, UCD is inherently inter- and multidisciplinary, drawing from a blend of psychology, computer science, artificial intelligence, linguistics, anthropology, and sociology,^[6] and in recent years particularly with web developments, graphic design, and animation as well as information science and business.

This entry first provides background on the genesis of UCD, following by a section on the philosophy and theoretical underpinnings of UCD, and then a description of the method as it is generally practiced.

Foundations

Traditionally systems design and development followed a system-centered, expert-driven methodology in which a set of requirements were defined at the beginning of a project, and the development process unfolded in a linear fashion from the list of specifications (i.e., what the system is supposed to be able to do) to the final product. This was adequate while systems were used by experts. With the emergence of end-user computing, users—the average people on the street—were unable to use products that resulted from such a process. The problems lay in the design of the user-interface, that part of the system that is visible to the user and with which the user interacts with the system. Users made mistakes, did not understand how to proceed, and could not figure out how to complete a task. The final assessment was that insufficient effort had been placed in understanding how users typically behave and perform the tasks for which the product was designed. In short, users were too much of an afterthought in the design process.

One of the earliest advocates of a focus on people first was Don Norman, a cognitive psychologist, who observed how people used many products including refrigerators, stoves, teapots, and doors as well as all sorts of electronic and digital devices.^[7] Norman noted the mismatch between what the system expected the user to do, and what users typically do when faced with possible choices. Sometimes the product lacked an appropriate affordance, the property of a product which suggests what to do with it (compare a door knob which suggests twisting, with a lever-style handle). Sometimes there were no visible cues as to what to do next or a mismatch between what the user expected to do, and what appeared to be available (consider even today's cell phones in which some phones are turned on by pressing “end,” or turned off by pressing “start”).

Sometimes the system provided no feedback as to whether anything had occurred when a user pressed a button, clicked on a menu choice, or issued a command (the “loading page” feedback mechanism within today’s web browsers show the extent to which the browser has loaded the page). In those early days (and to a certain extent today), the user’s conceptual model of the system, that is the user’s notion of how the system should work, did not match how the system actually functioned. Emerging out of this understanding was the need for more UCDs. “Know thy user”^[8] became the mantra, and often appended is the phrase “for they are not you,” a statement directed at system developers.

User-centered design can be traced back to the 1960s when human factors started to address the way that scientists and engineers interacted with costly large mainframe computer systems; this was primarily but not solely related to the ergonomics of the hardware. The concept of the interface was limited in scope, as the interface was solely for command-line interaction, in which the system provided a prompt, and the user entered a response or command; the cost was strictly in programmers’ time which was inexpensive when compared with the cost of the technology.

By the late 1970s to early 1980s, personal computers made word processing, spreadsheet manipulation, and simple graphics creation accessible to the person on the street. In 1981 IBM introduced its personal computer for home and small business users who had knowledge of the application domain, but no interest in the internal workings of the computer, unlike the typical computer users of the previous era. The concept of the graphical user interface or GUI (as in “goosey” as it was fondly called), emerged and, with it, the demand for more user centered technologies.

The need to support the end user brought an increased awareness of the need to understand simply how people function: their cognitive processes, including motor learning, problem solving, semantic memory, and perception, and how these processes affect peoples’ use of technologies. Human-computer interaction (HCI) emerged as a discipline and the Association of Computing Machinery established the Special Interest Group on Computer-Human Interaction (SIGCHI) devoted to promoting human factors in the human-computer interaction process. UCD and HCI are sometimes used interchangeably, but UCD is a methodology of HCI.

Two core publications of the mid-1980s focused attention on the UCD problem. Norman and Draper’s^[6] edited monograph, *User Centered Systems Design* emerged out of a workshop at the University of California, San Diego in 1984 (and included a blue ribbon group of human-computer interaction pioneers). In the introduction, the two editors expressed their goals for the book, which have become the underlying foundation of UCD:

We wish to...ask what the goals and needs of the users are, what tools they need, what kind of tasks they wish to perform, and what methods they would prefer to use. We would like to start with the users and to work from there.^[9]

This was, at the time, a novel idea; but this book was the first consolidated synthesis to an emerging concept. At about the same time, Gould and Lewis outlined three core principles for design that included a focus on users, empirical measurement, and iterative design.^[10] These have stood the test of time, and today serve as the basis for much of UCD practice. Emerging from this work was the concept of usability, and as already stated was not to be confused with user friendly. Making systems usable is a more complex construct that includes learnability, efficiency, memorability, being error-free, and subjectively pleasing.^[11]

The 1980s also saw the emergence of a new type of information system for the information consumer. With the introduction of CD-ROM technology, large bibliographic databases which were formerly only accessible to expert intermediaries and domain experts willing to learn a cryptic code were now reachable by working domain professionals (e.g., scientists, lawyers, doctors, journalists) who had limited computer expertise within months, the former databases that contained abstracts and bibliographic citations to published newspaper, journals, and technical publications evolved into full-text systems, also available initially on CD ROMs and later on mainframe systems with client-side graphical user interfaces.

At about the same time, how society, organizations, and culture shape the use of technology was being noticed. This introduced the importance of context: the situation in which the technology is being used affects that use and must be attended to within the design process. Suchman’s ground-breaking study of the lowly photocopier identified how situatedness affected human social behavior in the context of technology use.^[12] As a result, the need to integrate those influences called for more social and organizational analyses to be included in the design process. The concept of user incorporated more that the qualities of the individual.

By the 1990s, technology was not solely about transactional based technologies with structured data (e.g., numbers, codes) as its core; the emergence of the Internet and Web “informational” systems provided access to unstructured information (think text rather than numbers) that included ordinary homepages, newspapers, and the complete contents of books, journals, and videos. This placed new design needs on the concept of the user, the user’s task, and the environment in which the user was situated. With the emergence of the Web, the custodians of information—from publishers to libraries, from government to the not-for-profit sector and e-commerce—had to re-think and transform their existing approaches to systems development.

Surprisingly, early technological developments did not match expectations in terms of increased productivity. Landauer claimed that the problem lay with inadequate engineering design for application software which was due to the lack of systematic testing of technologies in terms of their actual utility.^[13] Instead he asserted that too much attention was focused on characteristics such as the speed of technology, its data storage capacity, the flawless operation of the technology, the number of features implemented, and its graphics quality. He argued for more testing of the ability of the technology to assist people in doing the work they needed to do. Despite the plethora of usability testing that was emerging at this time, Landauer claimed that too much of that testing was being devoted to aspects of the interface that would affect sales such as color and gadgetry, rather than addressing the formal functionality and usability of the system. Even today, customer satisfaction is considered the core success factor in assessing UCD processes internally.^[14]

By the twenty-first century, the focus was all about the user or customer, as e-commerce entered the arena; the economic consequences of non-user oriented technologies now had a direct effect on a firm's economic survival. Users now "marched" with their mice from one non-usable Web site or e-commerce storefront to another. With the emergence of the Web, social computing enabled users to not just march with their mice, but also to complain, comment, and compliment technologies and services in listservs, blogs, wikis, and consumer-oriented Web sites.

Companies and organizations could no longer hide behind a poor technology. Today UCD is practiced by a range of systems developers including IBM, Microsoft, Google, Apple, and SAP. It has been a cornerstone of operations within IBM.^[15] Within the information world, and libraries in particular, the concept of UCD came late, since most of the systems used by this group are produced by third-party vendors who have a limited marketplace for their products, and thus limited resources to apply to UCD. For example, it was not until 1990 that OCLC created its Usability Lab.

Emerging from this history was UCD as both a philosophy and a process. As a basic principle, UCD places the person—the user, and not the system at the center of systems development.

It is a process that considers cognitive factors (such as perception, memory, learning, problem-solving, etc.) as a core influence on a person's interaction with an object. This concept is as relevant to the design of teapots as it is to the computer mouse, word processors, search engines, and webcasting systems, and to the myriad of information appliances that are emerging in the marketplace.

PHILOSOPHY

Central to UCD is the conceptual foundation on which it is built. In this section, the three core concepts: information

system, design, and user referenced by UCD, are defined, and then integrated into the core theoretical perspective that underpins UCD.

Information System

Information system is a complex term. It is an application of computing and information technology developed to meet a defined need or purpose. The term is used to include the database and application programs as well as the procedures used to manipulate the database in concert with the application programs, and the hardware (e.g., computers, printers, telecommunication devices, and networks) used for processing data and information.

Information system is often identified with business applications, in particular, transaction processing systems such as payroll, book lending, and interlibrary loan systems. These could be classed as operational systems intended for planning and control within an organization. But the term information system is also used and continues to be used for both tactical and strategic information systems such as decision-support systems, executive information systems, and financial systems.

With the emergence of the Web in particular, information system is now used not just to reference transaction-based systems that manipulate structured data. When technology enabled mass storage and the ability to completely represent and present an information object (rather than just to access to its metadata), information systems enabled and facilitated many human information processes: finding, reading, synthesizing, evaluating, and so on of unstructured information. Now the range of tasks supported by information systems spans routine operations of, for example, automatic bank machines, to complex decision-making and problem-solving systems that require extensive backtracking and digressions.

This description above specifies the entire system, from a UCD perspective, the system begins with that aspect seen by the user—the user interface.

Design

User-centered design, as a philosophy, has its roots in industrial and architectural design. Design emerged around the fourteenth to fifteenth centuries, although there is no specific event to which this concept is attached.^[16] Design arose with "the separation of thinking and doing"^[16] after the work of master craftsmen, for example, was divided into architects and builders, and today that distinction can be used to separate designers from programmers in systems development.

The word design may be interpreted in multiple ways: on the one hand it specifies the process used, while on the other it references the arrangement of all of the components contained in the design. Design is imposed, and "only when the constituent parts of a whole have the

unique end of contributing to the consummation of a conscious experience, do design and shape lose superimposed character and become form.”^[17] Dewey was talking about art, but the same sentiment is true of systems design. Eames took a more pragmatic approach in referring to design as “a plan for arranging elements in such a way as to best accomplish a particular purpose.”^[18] The end product of a design is not purely a visual object, but a complex artifact that may support one or all of the senses depending on its purpose. From a systems design perspective, when all of the elements, procedures, and objects work in harmony, the system almost “disappears” as the user is “one” with the visible components.

In practice systems design stems from industrial design with a focus on the action and activities that define the purpose of the product. As such design involves a two-stage process: the first is a conceptual process to identify what the product is expected to do and how the action will unfold; and the second is the physical where the conceptual elements are rendered into real-world objects, such as layout, menu labels, icons, and buttons. The lines between the conceptual and physical are blurred in UCD.

User

Early users of information systems were experts who performed often routine and predictable actions with applications. They were technically trained and technically oriented, and more than willing to learn the arcane commands or procedures required to use an application. Over time, the user became anyone who applied a set of actions to a computing device, and the designer of a system was no longer comparable to the person who would subsequently use the application.

User as a concept has met with considerable discussion. Bannon pointed out very early in the development of UCD that a user was not necessarily a person who makes only casual use of a system.^[19] A novice or naïve computer user may be an expert in the application domain, for example, accounting, medicine; and, sometimes a novice in the application domain may be an expert computer user.

Instead, the word, user, is a generic concept that is intended to be replaced with a specific “job” or task function as in lawyers when speaking of legal information systems, or accountants when speaking of accounting systems. But a system might also have multiple levels of expertise as a citizen, mayor, or property inspector for municipal information systems. A typical user may be classed according to many attributes such as skill level (naïve vs. expert, e.g., a law student vs. a partner, a history undergraduate student vs. a history professor); and by nature of use (ad hoc or daily). Nielsen characterizes users along three dimensions: computer expertise, computer experience, and knowledge about the task domain.^[11] As a result, the concept of user is more complex than one

imagines which somewhat explains the nature of UCD methodology (discussed later on).

Particularly within the engineering community, the term “stakeholders” is preferred to reflect the broader group from implicit to explicit consumers of the system. Lodge,^[20,21] classed stakeholders into six types of users: governing body, sponsor, user specified, end user, input generator (the person who will enter data into a system) and the output receiver. This nomenclature tends not to be used within the human–computer interaction and information science communities.

Conceptual foundation of UCD

How design, user and information system are blended is reflected in the early thinkers of UCD. In what is now considered a seminal work, Moran posited that “to design the user interface of a system is to design the user’s model. The designer needs to understand... what knowledge goes into the user’s conceptual model”^[22] so that ultimately the user should not have to struggle to figure out what the designer intended. This led to thinking about how users act, behave, and perceive.

Card and colleagues^[23,24] proposed a “model human processor” that could be used by the designer in contemplating how a person interacts with a computer at the interface. The model included three human systems, each with its own memories and processes: 1) a perceptual system that connects a person’s sensations from the physical work to internal representations in the mind; 2) a motor system that translates human thought into physical actions; and 3) a cognitive system that retrieves facts, solved problems, and selects a suitable course of actions. Notably, for some tasks, the human behaves as a serial processor (clicking on a button in response to a display), while in others, the action requires integrated, parallel operations that engage the three human systems at once (reading from and selecting from, and finally resolving the information contained on a single webpage). In addition to describing how complex and dynamic a human is, Card and colleagues specified both the typical and range of values that could be expected in human performance. In doing so they provided a standard for the measurement concerns of Gould and Lewis.^[10]

At about the same time, Norman described a “theory of action” to assist in understanding how users use systems^[25] as illustrated in Fig. 1. In general, a user approaches a system with a goal likely dictated by the task to be accomplished, but personal to the individual. The goal is converted into an intention which is acted upon, and subsequently executed using the system. The system is in a certain state of readiness; imagine a computer that has just been turned on. The user perceives, interprets, and evaluates the response from the system. Norman claimed that the users’ goals and the perceived state of the system had to traverse two “gulfs” before users could make use of

Fig. 1 Norman's "Gulfs" embedded in his "theory of action" to describe how people interact with systems.^[26]

the system to achieve their goals. Thus, when the user approaches the system, the first challenge is what action can be taken to "bridge" the Gulf of Execution. When the system responds to a user's action, the user must now interpret that response to cross the Gulf of Evaluation. In using any system, this pairing of action and evaluation is a constant and continuous process.

Design needs to account for that process as the most elegantly designed systems fail when the user is uncertain about which action to take, or the system responds with a non-interpretable reply. At the beginning of a project (see Fig. 2), a designer envisions a conceptualization of the system, called the Designer Model, which is imposed on the system and is reflected in the System Image that is represented in the physical world by the user interface and represents the programmer's implementation of the designer's specifications.^[27] The user approaches the user interface with a preconceived notion of what to expect; we consider this the User Model. Designers' models consist of the ideas that the designers attempt to embody in a system; the users' conceptual model is a mental representation that is formed by experience—experience with older technology, the physical world, related applications, and so on.^[28,29] If the user's conceptual model is in line with the designer's model of the system, then the user is able to perform actions, and interpret responses made by the system. But when the two models are mismatched, the user is unable to bridge the Gulfs illustrated in Fig. 1. The degree of discontinuity is directly related to how well the designer's model and the programmer's rendering of it actually match the user's model of the system. The user interface serves as the "bridge" between these two conceptual models. In general, when the designer fails to take user needs and requirements into account in the design process, the system is unlikely to succeed.

User-centered design emerged from this awareness of the tension between the designer's view of the world and

Fig. 2 Designer, user, and programmers perspectives of the user.^[29]

the user's and is fundamentally the foundation for UCD practice. Over time, the focus on the user model morphed into the need for a full understanding of user in context—environmentally, socially, physically.^[12] In more recent years, affect, the user's emotional response to systems has also emerged as a core factor in design; it is no longer sufficient for a system to be fully functional, but now needs to be "attractive" and perceived by its users as attractive as well.^[29]

PROCESS

In addition to having a strong conceptual foundation, UCD defines a process—a practice or procedure—for the design of information systems. Back in 1985, Gould and Lewis^[10] identified three principles that would lead to a UCD system:

1. Focus on users and their tasks early in the design phase.
2. Assess and evaluate through the design/development process.
3. Use an iterative design process so that the result can be improved over the developmental life cycle.

These have been modified and augmented over the years, and Shneiderman's principles^[30] illustrated in Fig. 3 is one of the most parsimonious examples of these.

What is believed to be the first example of UCD in practice is the 1984 Olympic Messaging System designed to provide voicemail and communication support for athletes at the Games.^[31] The following brief synopsis of that work serves to illustrate the UCD process in practice.

At the beginning, an initial analysis of requirements was prepared and commented on by designers, managers, and prospective users. From this assessment, a number of functions that the system was expected to enable were modified, and some were removed. Simulations of these functions were tested and evaluated by the intended user

1. Strive for consistency.
2. Enable frequent users to use shortcuts.
3. Offer informative feedback.
4. Design dialogs to yield closure.
5. Offer error prevention and simple error handling.
6. Permit easy reversal of actions.
7. Support internal locus of control.
8. Reduce short-term memory load.

Fig. 3 Shneiderman's principles of UCD.^[30]

groups: athletes and their friends and families. In addition, site visits to the Olympic village and interviews with those involved with the Olympics brought new information and data. Finally a prototype was build and tested with a wide range of people. Over the course of its development from the initial concept to the first prototype (and subsequently the final product), the design followed the three principles developed by Gould and Lewis.^[10]

The UCD Process

Although practices may vary from organization to organization and from text to text, the International Standards Organization's standard, "Human-Centered Design Processes for Interactive Systems,"^[32] describes the core elements. Written at a high conceptual level, the standard is not prescriptive, but provides guidance in the form of a five-stage model illustrated in Fig. 4.

Plan the human centered process

As suggested by the title, the intent of this stage is the development of a plan for the succeeding stages, and for how the UCD process fits within the entire systems development project. This is a living document that is updated over the life of the project.

The complexity of the plan will depend on whether the system is an innovation (i.e., nothing currently exists), replacement technologies for an existing product (e.g., word processor replaced the typewriter, and the online catalog replaced the card catalog), or a new version of an existing digital product. Thus, in some situations, the knowledge of users and their context may already be known, or the existing technology may place constraints on the design such as an application that works in a Windows environment rather than a Macintosh, or a technology that will be an added component to an existing application.

Understand and specify the context of use

In this stage, understanding users and their tasks as well as the organizational and physical environment in which the

Fig. 4 UCD process as described by ISO 13497.

system will be used are the core components. These will subsequently guide design rationale and additionally prescribe how evaluation—success of the product—will be measured. The context of use is described in terms of:

1. Who the users are and what special characteristics they have.
2. What work tasks users will need to perform, and how those tasks are interrelated, including the allocation of human and technological resources needed to complete a task.
3. The matrix of user and task characteristics, so that specific scenarios of use can be described.
4. The context or specific environment (including physical and social characteristics) in which the system will be used.
5. The benchmarks that will be used to define both minimal and optimal requirements.^[32]

This stage identifies the range of intended users, the scope of their tasks and the contextual environment in which they operate. Central to this is an understanding of what the work is supposed to achieve; this is not about what the computer system is supposed to do, rather an explanation of the work task in isolation from the technology.

Specify user and organizational requirements

At this stage, the functional requirements of the system are specified with respect to users and the organization. What must the system do for it to be considered successful? This will describe:

1. Required performance of the new system with respect to operational and financial objectives, and to relevant statutory or legislative requirements (including safety and health).
2. Task performance and its integration with work design and organization.
3. Operations and maintenance feasibility.^[32]

This stage will document the design goals, guidelines and constraints, identify the priorities, and provide measurable

criteria for testing the design, including usability criteria (e.g., efficiency, effectiveness, and satisfaction levels).

Produce design solutions

This stage includes devising the rough concept through to sketching and developing a complete design. This requires integrating existing knowledge and technological capability with knowledge of users and the context. It may include visual design, information architecture, and interaction design. Potential designs are:

1. Created using existing standards, best practices, accepted guidelines and examples of other systems etc.) to develop a proposed design solution.
2. Rendered using simulations, low-fidelity prototypes, mock-ups, etc.
3. Evaluated by users who are observed performing specified tasks, with or without the assistance of evaluators, and modified from feedback.
4. Modified until design objectives (including usability objectives) are met.^[32]

This stage involves building a range of prototypes from low-fidelity paper prototypes, to high-fidelity prototypes that simulate the activity of the system.

Evaluate designs against user requirements

This stage evaluates the design with the user community using the application in a realistic environment. Depending on the number of iterations, this stage may be a formative evaluation intended to provide feedback to improve the design, or it may be summative to determine how well the system meets the criteria set out in the original plan.

These five stages are intended to be repeated as often as is required over the life of the project. Iteration and evaluation are considered critical to the success. In addition to the ISO approach, other variations have been well documented.^[33–35]

Each of these five stages uses a variety of methodologies to collect the essential data required to fulfill the requirements of that particular stage. For example, in understanding context (Stage 2), a collection of formal and information techniques are used to find out what the system is intended to do. This stage usually involves a visit to the workplace and an observation of how things are currently being done, as the way work is performed is often not like the way that procedural manuals stipulate. Observation and interviewing (formal and informal) together with careful note taking and sometimes videotaping provides a wealth of data from which to identify the issues. Stage 5, the evaluation component, uses a variety of techniques depending on how many iterations of the process have been completed. Early evaluation

techniques are more likely to be done with cognitive walkthroughs, and heuristic evaluation; later stages will do user testing with real users performing real tasks.

STANDARDS, PRINCIPLES, RULES, AND STYLE GUIDES

An international standard for UCD (previously discussed) specifies the design and development process, but is not the only standard relevant to UCD. ISO 16982 specifies usability methods that support “human”-centered design and is complementary to ISO9241-11, *Guidance on Usability* which identifies how usability can be evaluated in terms of user performance (efficiency and effectiveness) and satisfaction. This is somewhat related to ISO 9126 which defines six categories related to software quality for the software engineering community: functionality, reliability, usability, efficiency, maintainability, and portability, as well as the overall goal of achieving quality in use. Other related standards recommend specifications for usability of consumer products (ISO 20282), icon symbols and functions (ISO 11581), pen-based interfaces (ISO 14754), mobile—PDAs—tools (ISO 18021), multimedia user interfaces (ISO 14915) (55) and documentation (ISO 15910) and a format for writing reports of usability test results (ISO 25062).

In addition to standards, a variety of principles such as the ones mentioned earlier are used. In the actual conduct of design, a number of rules or heuristics are applied such as number of items to use in menus, color and font combinations, and layout. In addition, individual organizations have developed “style guides” to prescribe how design is accomplished for products developed by that group. IBM, Microsoft, and Apple all have developed style guides for the development of software. As a result, UCD has some consistencies in practice, but could not be considered a standardized methodology.

USE AND VALUE OF UCD

The term UCD is not exclusive; some groups refer to it as customer-centered design, experience design, or usage-centered design. Raskin^[36] distinguished between human centered and user-centered design. He claims a two-level design process in which the first stage is to ensure that the design relates to universal psychological attributes common to all humans, such as visibility of interface objects, amount of memorization that is acceptable, and human use of graphical elements. Once a system meets normal human physiological and psychological constraints, then the designers should attend to the task requirements of that particular user group. Raskin alleged that designers hand over responsibility for the human element to industry who is not always attuned to human capabilities.

The value of UCD is not universally understood or accepted. In a snapshot of UCD penetration among experienced practitioners, nearly three-quarters of respondents reported that UCD affected development within their organization and improved the usability of the final product.^[37] But, it also provided a picture of a methodology that was not universally adopted. Often cited as a barrier to UCD practices are resources and organizational resistance, because there are no clear metrics about how to assess a UCD process. These findings result from a survey distributed in 2000 and 2001.^[14] Undoubtedly with the growth in consumer digital products and the web, UCD now has greater penetration in organizations that produce consumer products. Ease of use for example, has been touted as the top factor contributing to conversion rates for Web sites, that is, getting customers to translate their visits into actions, or, in other words, purchases. Clearly in order to actually do that, one needs to adapt a UCD approach.

CONCLUSION

User-centered design is a process based on a strong conceptual foundation embedded in understanding how people function as human beings, and within the particular job function that a technology is intended to facilitate. The end product of such a process will provide a good fit between the user and the tasks that the user needs to accomplish, and the system that is intended to facilitate that activity. This is tightly integrated to a particular context that has social, political, and legal implications.

User-Centered Revolution: 1970–1995 [ELIS Classic]

Diane Nahl

Information and Computer Sciences Department, University of Hawaii, Honolulu, Hawaii, U.S.A.

Abstract

Nahl traces the increasing emphasis on an orientation to the user as central to information service design, information system design, and library education for professionals and end users.

—*ELIS Classic*, from 1992

THE NEW PARADIGM ESTABLISHES ITSELF

The user-centered revolution in library and information science was generated by the general availability of search technology for novice and users who rapidly outnumbered experts and intermediaries. The needs of this new class of searchers have changed the priorities in the information environment. In response, researchers have developed new types of data that more closely represent users' actual experience with systems. This interest led to an evolution in the methodologies applied to user studies over the past twenty-five years, from survey questionnaires and feedback forms to interviews, journals, logs, and case histories. The development in methodology represents a shift in focus from gathering anonymous, statistical data on users to individualizing users through ethnographic and psychological approaches.

With technology came transaction logs, a new online, real-time data-gathering method that records every keystroke of every user. Such logs have become a unique source of detailed information on what people do when they search. However, even this level of detail was not sufficient to understand why people make particular command choices and errors. Systematic self-reporting methods were introduced to obtain cognitive and affective data on reasonings, reactions, and decisions. Ethnographic studies using personal journals, protocol analyses, and self-witnessing methods uncovered the overwhelming quality of feelings in the research process. This new knowledge about users is driving the development of new systems and interfaces designed around user-centered principles. However, there was some resistance among designers, administrators, and librarians to the idea of taking care of novices' feelings.

User-Centered Versus System-Centered Approaches

The term user-centered arose in the minds of librarians and information specialists who wanted more services for end users, patrons, clients, students, and the public at large

within the information environment. They saw the status quo as "system-centered"; that is, insufficiently responsive to user needs and realities. One early observer notes the "growing movement" at the time for *user-oriented* systems to shift from "source-controlled" to "receiver-controlled".^[1] The expression user-centered has become a maxim—a principle—and represents a new paradigm for defining, measuring, and explaining the behavior of library users, database searchers, and Internet navigators. A search of the literature of the past two decades yields dozens of articles and some books bearing in their title or abstract one of the following expressions of this new orientation:

- User-centered
- User-friendly
- User-based
- User-oriented
- User-responsive
- Client-centered
- Human-centered
- People-centered

Two themes emerged in reviewing literature with a conscious user-centered focus: (1) methods of application that seek to alleviate specific user needs and (2) the integration of theoretical justifications and accounts that researchers have proposed for transforming the information environment through user-centered interventions.

It is worth noting at the outset that the system-centered approach in the design of information facilities routinely advises a testing procedure with actual users within the design process before features are finalized. However, this technique has proved to be inadequate, primarily because user categories have been based on designers' intuitions rather than on research about how users actually perceive, think, and organize and what their intentions are during the information-seeking process. As pointed out by Walther and O'Neil in the early days of online users, "Intuition and good judgment on the part of the designer seem insufficient for specifying the features which an

interface should possess” (p. 115).^[2] Despite this attempt to give users a greater weight in the interface design equation, system-centeredness has remained essentially the same. The reason for this is clarified in the discussion of the advent of the user-centered paradigm and its essential characteristics. In speaking of this basic shift, one commentator points to a distinction between the concept of information as “like a brick,” whereas users are like “empty buckets into which [information] bricks can be thrown” (p. 160).^[3] According to Dervin, the invalidity of this metaphor is shown by two outcomes; the “nonuse of information” by both professionals and the general public, and the user-oriented case studies of how people acquire and assimilate information in their daily lives and occupations. Reviewing the data, Dervin concludes

The important point here is, when it comes to understanding how and why and with what effect human beings pay attention to, process, and use something that an outside observer calls information, we must start by understanding what the user (or potential user) calls information. Information processing and use are, within the context of relativistic assumptions about information, sense-making activities. The emphasis here is on the word “making” for it denotes that the perceiver of the information is not an empty bucket but is actively making sense (pp. 164–165).^[3]

Information as an “observer construct” has had to give way to information as a “user construct” because the “empty bucket has evolved into a thinking, self-controlling human being” and “information changes from brick to clay, moved and shaped in unique ways by each perceiver” (p. 169).^[3] Because making sense of the world is part of the human condition, knowledge building is therefore a “personal information-seeking” activity.

Questions asked have dealt with locating self and other (Where am I? Where are they?), with finding possibilities (What can I do?) and evaluating possibilities (Will it work?), and with assessing aloneness (Is anyone listening? Doesn’t anyone else agree? Am I the only one?). Perhaps the most important aspect of the findings to date is that they support the premise that looking for information relativistically is a more powerful entry for understanding information needs and use (p. 170).^[3]

Looking at information seeking relatively requires one to recognize that situation-specific factors are more important to users than general considerations. For example, users’ interests and involvement (“issue oriented”) are better predictors of information-seeking activity than users’ education or experience. When individuals see their situation as giving them options for decision or movement, they are more likely to engage in information seeking than when they see themselves under total constraint (pp. 171–172).^[3] Another reason that information is “relativistic” is that “the effect of the information received is the use created for it by the user.” In other words, the situation-specific,

momentary information need determines what information will have impact at that time. Research in this new “relativistic information framework” can help systems designers make the shift to this user-centered orientation.

Replacing the Centrality of the System

In the early days of the new paradigm, there was not yet a full appreciation of the need to remove the centrality of the system. User-centered consciousness was not fully awakened until one saw the necessity of designing systems through understanding users. The following is an example of an early attempt to promote “an empirical approach to user-centered design.”

The problems which accrue to the human user by virtue of being made a component of the system—of the *user* actually being placed on-line to the computer—were largely ignored until very recently. A user protest led to calls for a shift of emphasis from the elegance of algorithms and computational efficiency to the discovery of ways to make the on-line user interface more acceptable to the user (p. 114).^[2]

As it turned out, more than “a shift of emphasis” was required. For instance, Walther and O’Neil define the flexibility of an interface as “the factors inherent in the interface program which would make it easier or more convenient for the user to express his commands, given that the commands had to follow a specific syntax” (p. 116).^[2] However, this orientation remains part of the system-centered paradigm because it passively accepts the priority or fixity of the system, although it recognizes that acceptability and convenience to users is to be taken into account. Another example is in the earlier attempts to use empirical or objective measures of *user satisfaction*. Researchers often turned to existing “attitude measures” such as the semantic differential,^[4] which provides subjects with a series of bipolar scales on which to rate their attitude toward aspects of the system.

The results indicate that the users of the flexible version [of the online editor], irrespective of any other factors, rated their version as more tolerant, more flexible, more like a person, more friendly, and more pleasant than the inflexible version (p. 117).^[2]

Future development of the user-centered paradigm will view such attempts as insufficient. Attitude scales have the following three inherent weaknesses relating to the object being rated, the timing of the rating, and its content. These problems need to be remedied by utilizing different techniques that avoid them.

First, the *object to be rated* by the user needs to be the user’s experience, not the system. Thus, *not* “On a scale of 1 to 7, how easy is this editor to use?” but rather, “On a scale of 1 to 7, how much confusion did you experience with this editor?” Second, the *act of rating* needs to be in

proximity to where the activity occurs, not at the end of a session, or even later, but concurrently, during the activity itself. Thus, more than a single probe is necessary, as a user's experience may vary greatly from one minute to the next, depending on various difficulties. Third, the *content of the rating* category must originate from the user's mental structure rather than the experimenter's, otherwise measures such as attitude scales, survey questions, census data, and personality tests represent system-centered accommodations to user protests of user-unfriendly systems.

More recent statements of user-centered system evaluation and design continue to promote the centrality of users^[5], but there is a shift in emphasis away from treating users as a method of determining baseline measures for design standards, toward “application-based evaluation procedures.” This represents an orientation toward operational effectiveness rather than design efficiency. In this view, system redesign can be motivated by how inconvenient it is to learn rather than how effectively it can perform under ideal conditions.

Criteria for User-Friendliness

Wallace has proposed a framework for evaluating the user-friendliness of a system.^[6] The list includes the following types of measures:

- Users must be given options for preferences.
- Online system operation and assistance should be available at beginner and more advanced levels.
- System behavior has to be transparent to users.
- Warning messages must be benign or lighthearted.
- System design must take into account the physical and psychological needs of users.
- System use should require no special skills.
- The general language of novices and their routine level of communicative skills should not be surpassed in instructions or explanations.
- The system should behave in a uniform way to allow users to anticipate functions.
- A variety of types of problem solving should be available for particular operations.
- Learning by doing should be the preferred mode of instruction and presentation.

One project that implemented these and additional user-friendly features is known as ELSA, “an intelligent electronic library search assistant.”^[7] Four design concepts guided the development of ELSA.

- Using labels that are transparent to users (e.g., buttons with the names “run search,” “new search,” and “show full list”)
- Providing assistance with controlled vocabulary (e.g., a synonyms list)

- Actively helping users explore topic areas (e.g., providing suggestions for narrower topics and screening out more distantly related items)
- Accommodating different styles of interaction (e.g., an option to type in search items or select them with the mouse from a list)

Another historical example is the user-centered redesign of the MELVYL system in response to empirically discovering the answer to the question, “What do users really want?” According to Farley,^[8] the process of collecting and maintaining a comment database optional to users has uncovered bugs in the system as well as numerous user-unfriendly features that could form the basis for redesign. Today, with Internet networking of libraries, MELVYL has learned to “compete in attractiveness” to users who are more sophisticated and computer literate, although still novice searchers.

The development of intelligent search assistants such as ELSA would not have occurred without the climate created by the user-centered revolution that gave it scientific legitimacy and made research grants available for user studies. The first phase of the transformation concluded when *user-friendliness* became a legitimate scientific research issue. An important thrust came from the human-computer interaction field populated by engineers, programmers, and applied psychologists.

Toward Human-Centered Design

In a whimsical mood, one of the architects of the user-centered revolution in the area of systems design and technology describes a still common attitude regarding the introduction of new technology.

One of the things that stands out when talking to long-term users of poorly designed systems is that these people take great pride in their skills. They had to go through great difficulties to master the system, and they are rightfully proud of having done so. . . . Rather than ease the situation for those who follow, it becomes a sort of initiation rite. The hardy survivors of the experience claim to share a common bond and look with disdain upon those who have not been through the same rites. They share horror stories with one another (p. 176).^[9]

Norman reveals that he “got attacked by hundreds of professional programmers across the country” when he wrote an article criticizing the UNIX system as user-unfriendly: “If I didn’t approve of UNIX, they told me, I had no business using it. Besides, who was I anyway to criticize computer software? In other words, you weren’t allowed to criticize unless you were a professional. Being a mere user of the stuff didn’t qualify” (p. 177).^[9] However, a new paradigm was in the ascendancy, and it is achieving full

victory. The user-centered revolution not only gives users more clout in the design equation but works to make users the *central* point of focus and interest for planners, backers, designers, engineers, and trainers of information systems.

Understandability and usability are two principles that apply equally to design and documentation issues. According to proponents of “cognitive engineering,”^[10] Understandability of instructions depends on providing a good conceptual model of the task or system. Good models are those that allow users to predict the effects of their actions. Users will invent false models when the appearance of some system features (the visible setup) does not match the functions desired (p. 16).^[10] The designer’s model is formalized by the design process itself. The user’s model evolves through interaction with the system. The system image consists of the visible structure or appearance of the interface (control, keys, instructions, labels, visualization aids or interface metaphor, etc.). All communication between designer and user takes place through the system image. If the system image does not make the design model clear, users end up with a wrong mental model as evidenced by symptoms such as an inability to predict, difficulty in using, a shallow understanding, and an inability to solve problems. One of the key factors in helping users develop an accurate conceptual model is to provide immediate feedback for every action or choice made.

User Errors

By studying the psychology of everyday actions, cognitive engineers have discovered many reasons why people make errors. First, one should note that people blame themselves for errors: “It is as if they take perverse pride in thinking of themselves as mechanically [or technologically] incompetent” (p. 35).^[10] Second, experience has shown that good system interfaces can be designed that make errors easy to detect and easy to reverse or, if not, have minimal consequences. Good designers heed the maxim: If an error is possible, someone will make it. One common source of errors is inadequate mapping, where users develop misconceptions in their mental models of the system. The existence of conflictual habits is another source of error (e.g., frequently hitting the wrong key for a particular operation). Users are reassured when they are reminded that making errors is routine in everyday automated activities such as keyboarding. Natural situations allow for routine correction of errors, such as retyping or abandoning a sentence midway and beginning a new sentence. This explains why error recovery procedures have become essential in designing computer systems in the user-centered era.

Norman (p. 107)^[10] has identified several types of user errors. *Capture errors* occur when a frequently performed activity suddenly takes charge instead of the intended one (e.g., hitting the wrong function key; hitting return instead

of an F key; waiting while staring at the screen without having entered the command). *Description errors* result from performing a correct action but on the wrong object, which occur when we are distracted, bored, or fatigued. *Data-driven errors* occur when the sight of some object or information intrudes into an action sequence (e.g., typing the wrong information on a line; choosing an unintended menu item). *Associated activation errors* occur when an association of ideas or thoughts triggers a nonrelevant action (e.g., typing an incorrect subject heading phrase). *Loss of activation errors* occur when the goal of an action is momentarily forgotten or when part of a sequence is temporarily inhibited. *Mode errors* occur when users forget what mode they are in when there are several (e.g., typing a command appropriate to another mode). Inherent in creating a user-friendly information environment is the requirement to discover what errors users routinely make, to expect them, and to provide accessible remedies for them.

For the first time in history, we are truly free to make machines that fit human needs, independent of mechanical constraints. New information technologies can enhance the power of human thinking, for machine plus person can do more than either alone, but only if the technology complements human abilities. We need more information-processing tools that complement our thinking, reasoning, and memory skills as comfortably as the calculator enhances our arithmetic skills. We can transform the hard technology of computers and information processing into soft technology suitable for people if we start with the needs of the human users, not with the requirements of the technology (pp. 52–53).^[11]

At this stage, according to one commentator, designers of information systems are now committed to a “user-centered design philosophy,” and have begun implementing interfaces that take into account “end-user information seeking needs.”^[12]

User-centered online design philosophy

Marchionini makes three assumptions about the characteristics of end users in electronic environments.^[12] First, end users are not interested in system characteristics such as design, elegance, or data structure. Instead, they want to get to the end of their work; they want answers, not pointers; they want document delivery, not information retrieval. A second assumption is that “end-users want to achieve their goals with a minimum of cognitive load and a maximum of enjoyment” (p. 156).^[12] This assumption echoes the law of least effort.

Moreover humans seek the path of least cognitive resistance and prefer recognition tasks to recall tasks; most people will trade time to minimize complexity. Finally, humans will perform better and continue to use systems that are pleasurable or interesting (pp. 157–158).^[12]

Computer-augmented information seeking can create a more relaxed, less stressful, more pleasant search environment. In other words, if it is user-centered, it is affectively more benign. In the past, attempts at designing more user-friendly information systems have led to software interfaces known as “metaphors,” such as the Desk Top metaphor for the operating system on Macintosh computers, and its competitor, the Windows metaphor. This approach has been applied more recently to developing alternatives to traditional command language interfaces. For example, Borgman and colleagues developed the “library metaphor” for an Online Public Access Catalog (OPAC) interface in an elementary school that uses the Dewey system and allows students to browse hierarchical graphic bookshelves (pp. 55–68).^[13] Some of the more recent search support innovations include the following, according to Marchionini’s review:

- Query-by-example^[14]
- Spatial database representations^[15]
- Online thesauri tied into the search command sequence^[16]
- Interfaces that offer suggestions to users, including dynamic queries that evolve as part of the interaction with the system^[17]
- Problem articulation as pruning (where users begin with all items in the database selected and each query results in a subset; e.g., computer library CD-ROM)
- Problem articulation “on the fly” through active browsing and judicious navigation in hypertext systems^[18]

Other developments include the addition of alternate input devices such as data gloves, gesture recognizers, speech recognizers, and eye trackers (p. 160).^[12] Marchionini quotes Gauch, saying that, “In electronic environments, the IR problem is not finding information, it is filtering information” (p. 161).^[12] This comment reflects a fundamental dilemma of end users in today’s information environment. However, novice users still do have great difficulties finding information because of their inadequate knowledge of search logic and vocabulary selection difficulties. Marchionini concludes that user-centered interfaces should accommodate individual differences, cultural diversity of individuals, and users’ affective and cognitive characteristics.

Writing Affective Point-of-use Instructions

The potential importance of help instructions in influencing the user’s affective information environment was demonstrated in an experimental study. Nahl showed that the stress and anxiety routinely experienced by novice searchers can be alleviated by adding a distinctly affective component to the instructions, consisting of providing additional orientation, advice, and reassurance.^[19] The importance of psychological factors in searching was examined by asking subjects to indicate on a self-efficacy

scale how confident they were in their ability to achieve a successful search outcome. Subjects who felt more optimistic in predicting a positive outcome has significantly better outcome scores than those who predicted low success for their searches. This suggests that optimism and self-confidence as a searcher empower users to better cope with the information environment. For instance, they found the instructions more helpful and comprehensible, they expressed more satisfaction with search results, and they spent less time per search. By contrast, searchers who expected low success expressed more frustration during the search activity, tried out a greater number of unsuccessful strategies, found the instructions less helpful, and spent more time per search. Fortunately, the pessimistic user self-orientation appears to be modifiable.

Optimism in searching is a learnable affective skill that involves generating positive self-regulatory sentences throughout the searching process. Point-of-use instructions and online Help facilities can either ignore this aspect of the user’s environment, or they can attempt to deal with explicitly. Future research will have to discover the specific verbalizations that need to be added in the form of elaborations to the instructions so that searchers will come to expect probable success rather than probable failure. One approach might be to identify what verbalizations are used by novice searchers who operate under a positive role model through think-aloud protocols, and then to incorporate these sentences in point-of-use instructions (p. 187).^[20]

Because the affective information environment is dynamic and challenging, users need to be taught coping skills that reduce stress and errors.

Written point-of-use instructions and online help screens provide good opportunities for user-centered interfaces to deliver both cognitive and affective information services. As reviewed by Nahl,^[20] user-centered consciousness in the area of software documentation and help instructions first took the form of “minimalist,” advancing the principle that verbose text is tedious, confusing, and repelling to users in general. Shorter, well-organized, and indexed manuals are not only preferred by users but are also less costly to produce. This trend was beneficial, as it enabled systems professionals to focus on what users prefer in terms of length or detail and easy-to-understand language.

A sample of written point-of-use instructions for CD-ROM database searching typical of university library handouts was analyzed and found to be minimalist in both cognitive and affective information, but especially the latter.^[20] Breaking minimalist principles in user instructions, Nahl edited and lengthened an existing point-of-use instruction sheet by adding sentences that served as “affective speech acts,” providing users with extra orientation, extra advice, and plenty of reassurances. The elaborated version was three times longer than the former but was rated significantly more helpful and comprehensible to subjects in a controlled experiment.

Perceived Self-Efficacy as a Searcher

An interesting and unexpected finding from the preceding experiment was that novice users enter the search situation with definite beliefs about their probable success. Subjects were asked to review five search tasks they were about to perform and predict their probable success. The group was then divided for analysis into two subgroups, namely the upper and lower halves in terms of self-confidence as searchers. The results showed significant differences in all of the dependent measures of user behavior, despite the fact that the students in the two subgroups did not differ in searching or computing experience. Novice users who had higher expectations of search success also had higher retrieval scores, expressed greater satisfaction with results, felt less frustrated during the searching, were more effective in their search strategies, and were more efficient. Rather than viewing these features as permanent psychological or demographic differences, Nahl sees a searcher's self-efficacy beliefs as a learned mental habit that, with effort and instruction, can be further developed.

Nahl relates these findings to prior research and theory on *self-efficacy beliefs*^[21,22] and *speech act theory*.^[23–25] As users engage in the act of searching, a continuous stream of silent verbalizations is produced as a means of making things understandable, and as a by-product of their affective involvement, by taking charge, users can consciously manage these sentences and use them to regulate their behavior.

One method of self-control involves the use of self-regulatory sentences thought to oneself. *Self-regulatory sentences*, viewed as habitual speech acts of users in a learning setting, can be witnessed and deliberately changed in self-modification attempts. “Learned optimism”^[26] is an affective habit some users evolve by acquiring an “optimistic” style of talking to themselves during searching by expressing greater self-confidence in a successful search outcome. “Learned pessimism,” on the other hand, is a habit of “helplessness” in the face of challenge and apparent constraint. Users who have low self-efficacy beliefs as searchers have acquired “pessimistic” habits of thinking and express lower self-confidence in their search success. Because habits can be retrained, Nahl suggests that instructions and help assistance contain advice and reassurance that counteract negative self-talk and help users establish more adaptive self-regulatory speech acts while operating in the information environment.

Boolean Pitfalls

One of the stumbling blocks for novice users of online systems such as CD-ROM bibliographic and full-text databases is that search principles operate by Boolean logic, which at first may seem counterintuitive. For example, in ordinary language, a query problem may state

“Search for articles on the dangers and risks of caffeine and caffeine products to pregnant women.” One possible solution might be the search statement:

(danger OR risk) AND caffeine AND pregnant women

Note that in Boolean logic, the *and* between “dangers and risks” requires a transformation to the OR operator. In “caffeine and caffeine products,” the words and *products* should be ignored. Transforming that AND to OR would not be a fatal search logic error, but in ordinary language, it appears to novices as if the search statement should read as follows:

dangers AND risks AND caffeine AND caffeine products
AND pregnant women

In the words of one novice attempting to think in Boolean: “You need to find out about both caffeine and caffeine products, so you need to put AND between them.” However, this search statement is not likely to produce the expected results.

There is evidence of the occurrence of a leakage between the semantic and the logical features of Boolean cognitions. Semantically, both caffeine and other caffeine-related products are of interest here, and it is true; however, the operational logic of searching requires the OR operator if either subject is wanted. In order to block semantic leakage from influencing the logical requirement, a cognitive transition must take place in which the primary focus is on searching the text of records rather than on the semantic features of the topic. This semantic to search logic transition may at first seem contrary to ordinary thinking.

As pointed out by Nahl,^[27] composing valid Boolean search statements depends on an accurate understanding of both the semantic and logical features of the operation. Searchers must learn to keep intact the boundary between these two aspects. There must not be any leakage in the rational “membrane” that separates the semantic from the logical functions. The following example shows how one novice searcher, after reading the instructions, did not separate the semantic aspects from the purely logical features of a Boolean search statement. The task was to:

Circle the concept(s) that must appear in every article retrieved by this strategy: (driving behavior OR drivers) AND risk-taking

The subject inaccurately circled “driving behavior” and wrote the following explanation:

Because the interest is in driving and correlation to behavior, style, motive, etc., I feel that the circled concept must be in every article.

In operation here is the act of reasoning by similarity instead of reasoning by search probability logic. The

problem should have been solved purely from the perspective of formal Boolean logic [i.e., (A OR B) AND C, requiring that concept C appear in each of the retrieved records]. Instead, *semantic leakage* from the topic “driving” led this novice to ignore the necessary logical implications of the Boolean connector. Data such as these indicate which aspects of Boolean reasoning need to be specifically explained and taught.

User-centered online design philosophy must take into account several dynamic factors. Some researchers point to the need for accommodating individual differences, cultural diversity, and affective and cognitive characteristics. Novices need different types of elaborations in oral and written instructions for using systems, especially those that provide orientation, advice, and reassurance. Even the self-confidence of novice searchers plays an influential role in their style, success, and satisfaction. Avoiding Boolean pitfalls and understanding search logic cannot be left to self-instruction. The recognition that users require training that incorporates all of these dynamics has led to a change in public awareness.

THE PUBLIC SECTOR

In the area of library management, one study refers to “a user-oriented approach” when priorities for library services are set through the use of survey data^[28] comparing the budgets and opinions of three special library directors with the research staffs of three organizations as to their attitudes and priorities. Surveying users to get data relevant for planning information services is a response by the system to calls for becoming more user-centered. An early expression of the user-centered paradigm is found in the work of Parks,^[29] who focused on information needs in the public library sector for the handicapped and the elderly. Parks identifies the passage of Titles IV-A and IV-B of the Library Services and Construction Act as marking the beginning of a new community attitude and practice toward the institutionalized and the challenged in our society. This trend has seeped into the *physical* environment of libraries (e.g., signs, central floor plan, electric-eye doors, color, plants, fish tanks) the *organizational* environment (e.g., hours, formal teaching, special programs), and the *human* environment (e.g., social climate, group rituals, flexibility, individualized response, initiative, poise). The passage of the Americans with Disabilities Act continues to deepen this trend.

The Role of Technology

Two factors seem to drive the movement of the user-centered paradigm shift: the rapidly increasing number of novice end users and changing technology. These two factors are interrelated. An increasing population of novice users and greater technological complexity combine to

exert social pressure on the managers of information environments. The role of technology was described this way by a library educator.

In short, this is an era of stressful change brought on by convulsive waves of shifting values on every front. Change is not new to libraries, of course, but what is new is the collapsed time-scale of change. In the past change was faced as it happened, but lately social and technological alternatives have occurred at so great a rate that change must be dealt with continuously. The order of change is entirely different from anything which came before. Whether one calls this change revolutionary or evolutionary hardly matters; what counts is the degree to which such change will affect the library’s role in society. As one librarian put it recently, “the trouble with our times is that the future is not what it used to be” (p. 409).^[30]

A recent review of Ranganathan’s 1928 “Five Laws of Library Science” shows where these principles operate today within the new information technology. According to Sharma’s analysis, new technology “is enabling the realization of Ranganathan’s vision of user-centered, user-friendly information service implied in his Five Laws” (p. 258).^[31]

1. Books are for use.
2. Every reader his book.
3. Every book its reader.
4. Save the time of the reader.
5. The library is a growing organism.

The *open access* technology has enabled realization of the first law as embodied, for example, in online catalogs that “show whether a document is on the shelves of the library or not; and if charged out, when it is due back in the library” (p. 260).^[31] *Resource sharing* and networking have helped validate the second law, and the third law is facilitated by cross-references and keyword search modes in online databases. Finding information in the shortest possible time with online searching, full-text, and CD-ROM technology serve the fourth law; planning and organization of libraries can promote the fifth law. Realistically, these laws are potentiated by new technology, but technology must assist users in more significant ways before these laws can be attained.

With the new networking technology, “information space” has become so vast that new methods have been invented to allow users to “navigate cyberspace.” Various “browsers” introduce their own problems in usability. Old skills for reading paper formats and sequential paging habits have to be modified and applied to screen-presented text, scrolling, and hypertext linking within and across documents. Text formatting, color, highlighting, and speed of access have become important user-related considerations that influence the quality and success of “surfing sessions” on the Internet.

Futures Planning

Those who plan for library services for the next century have adopted a clear user-centered focus. For example, Shapiro and Long (p. 286)^[32] advocate the “reengineering” of user services in academic libraries by spelling out a number of principles.

- Recognizing and dealing with the whole range of user needs (i.e., reference service, telecommunications software assistance, and searching difficulties).
- Transforming services staff into information “case-workers” so that librarians try to maintain postconsultation follow-up procedures to track what happens to users after they have been referred to other specialists.
- Process or procedures must be developed to suit users rather than organizational structure, and continuous change based on feedback or evaluation is essential for effectiveness of information delivery.
- Information technology must not be used merely to provide access through automation but to assist users, such as automated problem-tracking systems and information desks or kiosks.
- Collaboration across the campus with faculty groups and the computing center is essential in producing “symbiotic” operations in support of users.

One study investigated what users of a university library think libraries of the future should be like. The most frequently cited “critical” use of the ideal library of the future was “speedy retrieval and simplicity of use” (p. 307)^[33] Other desired uses included computerized catalog, online searching of databases, full-text retrieval, wide availability of terminals, remote access, twenty-four-hour availability, and personal library assistance services. Another commentator on types of services that would be offered in “user-responsive research libraries” warns that

Some futurists foresee them becoming outmoded storehouses of printed materials, repositories that lie outside of the mainstream of academic life. Others predict that they will become vital information centers, growing more central to research and teaching as the information world becomes even more complex. A cogent case can be argued for either of these opposing extremes, but the final outcome is still beyond our field of vision (p. 59).^[34]

To ensure a positive final outcome to the user-centered revolution, the following system features are recommended for the electronic information environment:

- It should be more access-oriented, less size-oriented.
- There should be universal adaptation to the technology by the entire library staff.
- Personnel should give up the myth that researchers and scholars are skilled users.

Dougherty calls for “a significant overhaul of the duties of most reference librarians and bibliographers” to assist them in developing a better understanding of faculty information needs, their information-gathering habits, and their service preferences.

Customer Service Philosophy

The knowledge needed by information workers to deliver adequate services has become quite broad, according to a recent textbook that addresses “customer service in the information environment.”

It is Mr. St Clair’s premise that the information services practitioner must be broadly defined to include persons engaged in every aspect of information service from records management to technology-based information transfer. The connecting link in all of this information work and the basis for this book is that user needs determine the nature of the information service and that the user’s knowledge of the subject area is a critical component in determining how the information services practitioner will organize the information and make it accessible in the most efficient manner possible, (from the foreword by John Ganly).^[35]

The recognition that information systems should represent how users think rather than how librarians organize information has become the cornerstone of the new paradigm. The “new philosophy of service” aims for “the provision of quality information to its customers,” including such customer service mottoes as the following:

1. People come first.
2. We give accurate and reliable information.
3. We are serious about our high level of service.
4. We cannot afford to give one wrong answer.
5. We are accessible and easy to approach.
6. We are doers—we work hard.
7. We are often pleased but never satisfied.
8. We want our staff to be happy working for us.
9. Service is a state of mind. People must care and have a desire to do it right and to do it now.
10. The client is always right.
11. Everyone must be thinking about how to do his or her job better and more effectively.
12. Enthusiasm and faith are necessary to remove barriers and increase productivity and decrease costs (pp. 5–6,^[35] attributed to Meg Paul).

This new philosophy of information service strikes some librarians as a model more appropriate for commercial settings than academic and public libraries.^[36] This conflict illustrates how the new user-centered paradigm is being extended. It appears that new technology, in such forms as the Internet and World Wide Web, has deepened

the connection between marketing principles and library and information services. This shift is reflected in the historical sequence of designations referring to recipients of library and information services: readers, patrons, clients, end users, and customers. “Customer” service in the information environment brings marketing principles to librarians and information specialists.

Central to the new marketing attitude of information provision, whether for the corporate library or public school multimedia lab, is the “information audit” or user survey. Needs analysis identifies the character of the constituent user groups. Focus groups can help determine what kind of information delivery users prefer. Test runs reveal which procedures users resist or are reluctant to follow, or that produce errors. User surveys elicit responses and comments by potential users. In considering the question of why the wishes of the information consumers have not been better taken care of in the past, St Clair points out that

We have been remarkably successful in using technology in the organization of information, and we are justifiably proud of our long history of using information technology in creating information products and services *for our customers*. What we haven’t done is to use the same technology for creating programs to help us learn more *about* our customers. We haven’t taken the time because we’ve been so busy developing the information products that we forgot who we were developing the products for (p. 93).^[35]

“User-oriented evaluation” (UOE) has been promoted as *action research* “carried out with the aim of generating information which may be used, in some way, to improve information systems and services” (p. 93).^[37] UOE methods include test searches, user attitudes, failure analysis, case study, microevaluation, and other forms of situation-specific qualitative and quantitative analyses. The complexities of studying the user in the information environment require new and more intensive methods.^[38]

The user-centered trend is creating a basic revision of library management and operation in the form of incorporating user input at various levels as a structural component of the management process. One expert advises a phasing-in process starting with the creation of a collection development committee with liaisons to faculty and jointly established written procedures.^[39] Collection vendors would be invited to receive input from the joint committee. Similarly, faculty would serve on a serials development committee and initiate procedures for campuswide departmental input. The structural integration of users into the management fabric itself creates the “client-centered library” (p. 351).^[39]

The Role of Legislation

Legislation and community attitude are important influencing factors in shaping information institutions to

their users. In 1979, the board of the Association of American Library Schools set up a task force to examine the implications of the White House Conference on Library and Information Services,^[40] in which the principal theme was a reaffirmation of free and full access for all citizens. Although the members of the task force recognized this thrust and supported it, they felt that even more needs to be done, such as “recruiting to the profession representatives from the information impoverished, who may have the advantage of instant credibility with their constituencies” (p. 250).^[40] At least one of the “elements of a comprehensive national library and information services program” was explicitly from a user-centered point of view, recognizing the idea that *access* includes *education*.

A-5. Access to Library and Information Services

That institutions educating library and informational services practitioners assume responsibility to address the need of said consumers through their training and education, and that guidelines by appropriate governmental leaders establish standards of in-service training and that training standards for library professionals be implemented without delay

In other words, librarians need to be educated in how to instruct users to gain access to filter and evaluate information.

Educating Information Specialists

The education of future librarians to function in technologically reengineered library settings is addressed in a study describing “a model of how academic libraries and schools of library and information studies (LIS) may collaborate to provide useful education experiences to LIS students and reliable reference services to library users.”^[41] Students study and apply information-retrieval principles and reference interview theory, as well as “role playing, analysis of frequently asked questions, and philosophy of information service” (p. 292).^[41] The emphasis is on the case-study approach, as students were required to follow up on the advice and instruction they gave to library users, to test its efficacy, and to study the entire information-retrieval cycle.

In both the courses and the fieldwork, students were urged to accept a client-centered philosophy of reference librarianship and to view library users and librarians as linked in the research process. Students were encouraged to be approachable at the information desk, to look out for people who might need information, to ask follow-up questions in reference interviews, to encourage people to return to the desk to go to another service point for further assistance, and to express a variety of user-centered values and attitudes while at the information desk.

This reference fieldwork allowed LIS students to gain experience in answering online catalog and directional

questions at one of the library's busiest information service points. The experience enabled LIS students to make the immediate connection between the theoretical content of the course and the actual experience of reference work in a large academic library. The students consistently expressed their appreciation of this integration of theory and practice that allows them to try out various principles in vivo and receive immediate feedback from library users.

The two factors driving the user-centered movement are the increase in the number of novice end users and the rapid change in technology. Future planning in library services for the next century supports a clear user-centered focus. The customer service philosophy, although not acceptable to everyone, nevertheless points to the recognition that information systems should represent how users think rather than solely how librarians organize information. Legislation, community attitude, and education of information specialists are moving toward a client-centered philosophy of reference librarianship. The increasing social consciousness of the importance of the user cannot by itself create an intellectual revolution unless supporting scientific theory evolves along with it.

COMMUNICATION THEORY

Sense Making

One of the earliest statements defining the concept of user-centeredness is attributed to the critique of Zweizig and Dervin, whose approach is based in American communication research.

Since the 1970s, critical attitudes toward the narrow conceptions germane to a system-centered approach were evinced. Institutions such as libraries distributing information were seen as instruments serving information seeking and use, not as an end. The critique was made explicit by Douglas Zweizig and Brenda Dervin, precursors of the *user-centered approach* to information seeking and use. They proposed that instead of asking who is using the library or how much is the library used, the question should be for what purpose was the library used and how did it help? Thus the important question would be not library use, not library users, but library uses.^[42] Since the late 1970s, suggestions for a refocus of research on the individual actors seeking and using information in practical social and cultural contexts have become more frequent [see, e.g., 43–45]. Today we see that these efforts have been successful—the user-centered approach is about to offer the traditional intermediary-centered approach a serious paradigmatic alternative (p. 14).^[46]

Sense-making research investigates behavior, both internal (i.e., cognitive) and external (i.e., procedural), allowing individuals to construct and design their movement through time-space. Sense-making behavior is thus

communication behavior. Information is the sense that is created at a specific moment by an individual. Information does not exist apart from the subjective, constructive process. The central activities of sense making are information seeking, processing, creating, and using. Sense making is a process; sense is the product of this process. According to Dervin, “sense” includes “knowledge,” but also a host of other subjective factors that reflect an individual's interpretations of a situation, including “intuitions, opinions hunches, effective responses, evaluations, questions, etc.” (p. 16).^[46] Thinking and perceiving are referred to as “moving forward in the cognitive terrain.” When there is a lack of relevant information or there is confusion and uncertainty, routine thinking no longer works effectively, and a situation called “gap-facing” arises and elicits “gap-defining” and “gap-bridging” activities. People evaluate their gaps differently; “optimists” may see no problem where “pessimists” are stumped. They may differ in “rigidity” or “flexibility” in their gap-bridging.

Dervin's sense-making concept, defined as the “movement of thoughts and questions through cognitive time-space,” is explained by another commentator as follows:

In this sense, one may be said to move through a series of thoughts and experiences, to encounter “barriers” to one's progress, to “lose” one's way, etc. In either case, any given movement can be interrupted when an individual is confronted by the need for some form of guidance; that is, when they need to know something. Based on the work of Carter,^[47] such conditions are considered cognitive “gaps,” and may be exemplified in their most general form by the need for street directions or instructions on the use of Boolean connectors, depending on the behavior context. Information seeking is defined within this framework as “gap bridging.” Gap bridging can be accomplished by thinking up an answer, asking for help, looking for useful information, or by any other functional method that enables the individual to continue moving. These gap-bridging attempts are operationalized as “questioning,” whether spoken by individuals or unspoken (p. 649).^[48]

In an attempt to apply Dervin's sense-making theory to the day-to-day operation of a library, Morris asks such basic questions as, “What does it mean to have a user-centered reference service?” or “What should a user-centered approach to cataloging entail?” (p. 20).^[49] User-centered in this theoretical context means viewing information as something “construed by users” and designing systems and services that are tailored to how humans think and feel when processing information to meet a need. This is in contrast to the traditional system-oriented definition based on the work of Shannon and Weaver^[50] that views information as having an objective existence outside the individual.

When we seek information through the traditional paradigm, our goal is to find the external “information reality”

that corresponds to our internal need. As Dervin points out, we don't talk as if we hold this traditional view of information. On the contrary, we admit that knowledge isn't absolute, that what really matters are people, that people change, and that a message sent doesn't equal a message received (p. 21).^[49]

In the sense-making model, information becomes “whatever an individual finds ‘informing’ ” (p. 22).^[51] Information triggers changes in the user's perceptions, which alter how the information is perceived. The user is seen not as a passive receptacle but as an active participant in a constructive process of information processing. Although users are unique individuals, there is a common or universal process through which all users pass in adaptation to a particular information activity. Addressing user-centered services to these commonalities requires scientific knowledge about the actions, thoughts, and feelings that constitute the experience of being a novice user.

According to Morris, a primary goal of information professionals should be “understanding and clarifying ambiguous information needs” (p. 25).^[49] Ambiguity and uncertainty can be unpleasant and stressful feelings; hence, library services such as reference interviews need to be negotiated by librarians with a view to “intervening” in the person's state of information challenge. Vague requests, or those that are too broad or too narrow, may require probing with open questions, addressing the need behind the demand rather than the want or demand as first formulated by the user. An interesting point raised by Morris is that users tend to operate under the system-centered paradigm in their own views of what information is or what the process of finding it is like. The self-contradictory nature of users is captured vividly in the following description:

The picture of the individual that emerges from these studies in psychology holds complex implications for a user-centered, constructivist model of information. Humans are, by their nature, contradictory: drawn to make quick decisions that reduce uncertainty but struggling to understand clearly enough to make a good decision; striving for order, but enjoying the intellectual challenge of disorderly facts and unconventional ideas; needing the familiar, but craving the risk of the unknown; unable to express what is needed, but nonetheless perpetually asking questions; highly knowledgeable, but unable to transfer that knowledge. This is the user whom we wish to serve (p. 29).^[49]

In a radical proposal, Dervin^[52] urges that we abandon the traditional system-centered categories of users such as demography (age, race, education, gender), personality (cognitive styles and preferences), ability or literacy levels (language, computer, knowledge), purpose for using the system (information, entertainment, research), and user-satisfaction ratings. Such categories, Dervin argues, “lead us to a view of communication systems that makes haves and have-nots inevitable” (p. 217).^[52] The “haves” are

those who successfully use the system, whereas the “have-nots must somehow get more of what they lack—education, money, literacy, motivation to read news, computer skill, cognitive complexity, etc.—so that they can become like the haves” (p. 217).^[52]

Revising User Categories

Dervin proposes a radical redesign of the information world based on a deliberate refocusing of the nature of user categories.

The actor's situation. This category of user behavior identifies “why in a given situation a person tries to use an information or communication system” (p. 225).^[52] How complex is the situation? Is it a piece of a larger project? Under what constraints is the user operating? What barriers does the user perceive?

Gaps in sense making. A query points to some gap in information and the outcome of a search yields a message that can help close the gap by constructing new meaning or new understanding. An information gap is not to be defined by topical categories or subjects, as in the system-centered orientation. Instead, gaps are “gaps regarding the characteristics, aspects, or dimensions of self, others, objects, events, timing, spacing, causes, consequences, and what-ifs” (p. 225).^[52]

Actor-defined purpose. System-defined purposes for “looking for information” traditionally include such broad categories as information, entertainment, social, cultural, and escape. User-centered purposes are more situationally specific, such as “getting pictures (cognitions), finding direction, gaining skills, getting motivation, avoiding bad places, getting out of bad places, getting support, getting connected, achieving goals, getting happiness, getting rest” (p. 225).^[52]

Information-Using Strategies, Values, and Traits

User strategies are adaptive mechanisms that people employ in searching for and using information. These include “browsing, formatting, grouping, highlighting, indexing, citing, digesting, abstracting, formulating, transmitting, interpreting, connecting, and skimming” (p. 225).^[52] “Actors” (i.e., searchers) evaluate information in terms of its meaning to them; that is, its “timeliness, breadth, adaptability, accuracy, specificity, touchability, moveability, and newness” (p. 225).^[52] The term “information traits” covers “the specific characteristics of how the user would like the information presented,” such as quantitative data versus qualitative assessment, precedence setting versus futures planning, hard facts versus opinion, single point versus options, and clinical observation versus census.

When comparing traditional user categories with these user-centered dimensions, a clearer view emerges of how

the information world needs to be redesigned to make it more serviceable to users in terms of instruction, assistance, and organization (cataloging and indexing). In terms of *user assistance*, build a focus on user categories. Under what constraints is the user operating? Is the user more interested in gaining an understanding of something specific or exploring without a fixed goal? At what stage of the seeking process is the user at this time? Does the user want to take the information home? Does the user want to see hard facts only or is there an interest in clinical studies also?

In terms of user-centered *information organization*, the focus is on indexing content in terms that users can recognize in relation to their momentary and variable intentions and motives. How do I just browse? How do I reformat this text? Where do I find a citation for this? What would help reformulate this? Where can I find a digest of this? I need to see an interpretation of this (and so forth). A user-friendly environment anticipates and accommodates, facilitates, reassures, and above all, delivers and satisfies. To achieve the goals, information professionals have developed methods for identifying and measuring users' behaviors—their actions, thoughts, and feelings during the information-seeking or knowledge acquisition process.

MODIFYING USER BEHAVIOR

Learning Principles for Searcher Self-Modification

A number of writers in the field of library science have urged the application of learning theory principles to library instruction and services.^[53–55] The field of psychology has broadly discussed the “conditions of learning” that need to be present when acquiring new habits, and some of these were summarized for the narrower field of acquiring information retrieval skills.^[55]

Sufficient motivation for learning

Search behavior is goal-directed behavior hierarchically organized so that subgoals constitute larger goals. For instance, looking up a word or entry in an index is a subskill within the larger skill of locating a document. The subskill requires the searcher to inspect the list, look up and down, page through, select terms, and so on. This subskill has its own goal and motivation. If the searcher lacks sufficient motivation to persist in the look-up operation, the subactivity will be prematurely abandoned, with negative consequences to the overall search effort. A single global assessment or rating of a user's motivation or interest in completing a task is thus unlikely to predict accurately a person's multiple motivational requirements with all the subtasks. The information environment needs

to be designed to encourage and facilitate the emergence of sufficient motivation at multiple levels of administration and instruction.^[56]

Active responding

Instruction must provide for some form of responding or active participation from the user. In the sensorimotor domain, locating an item on a computer screen is a prerequisite skill that needs to be practiced beyond some minimum level before one can expect users to have success in finding information. In the cognitive domain, users need to be given learning opportunities to rehearse reasoning sequences such as “What would happen if I do X?” or how to redirect a search strategy that is not effective. In the affective domain, novices need to be given the experience of overcoming an information challenge by helping them complete a task or operation successfully.

Providing reinforcement

In the educational and clinical psychology literature, a “reinforcing stimulus” is an incentive that works; that is, if that reward is systematically applied in a teaching context, learners will acquire that target habit more quickly. Of course, some incentives do not work. One guiding principle is to discover what users find relevant and rewarding in specific information situations. Although it is universally recognized that rewarded repetitions lead to learning new skills, given the hierarchical organization of information skills, global rewards are not always sufficient to maintain consistent reinforcement. Sometimes too much emphasis may be given by users and professionals alike to the end result or to overall search success. If this is unsatisfactory, a general negative pall is cast over the entire information-seeking enterprise. Instead, users can be *taught to appreciate* the little successes within the overall (temporary) impasse.

Reinforcement strengthens the behavior to which it is applied. The repetition and rehearsal that occur with hands-on experience become opportunities for applying reinforcement and evolving a routine habit. These experiences need to be instructionally managed to provide sufficient success for subactivities. Both external and internal levels need to be considered by information professionals. Special attention must be given to *self-reinforcement* activities by searchers, as explained in this description.

Search behavior continuously operates to overcome the aversive stimulus of unfulfilled information needs. Every subactivity is accompanied by affective and cognitive reactions. Success builds self-esteem; failure engenders depression. Part of BI [bibliographic instruction] might be teaching patrons how to “self-reinforce” during searching. Many patrons are ill-equipped to deal with the emotions that are aroused during searching. They may engage in

damaging self-talk, making self-accusations such as: “You stupid fool. Why did you forget to write that down?” or “I’ll never get this done in time.” BI could therefore include the teaching of appropriate self-talk such as: “It is normal to feel confused in the beginning of a search” or “Other people make the same mistakes.” Teaching students to use self-reinforcing “speech acts” while searching is part of encouraging independent learning skills; the librarian’s words, if not the librarian, are present to guide and regulate search behavior (pp. 79–80).^[55]

Broadening user instruction to include motivational skills and self-regulatory speech acts may appear to some information professionals as too personal or even invasive. However, from a user-centered perspective, the new inner focus on users is both legitimate and beneficial to their needs, preferences, and growth potential in life long holistic information activities.

Search Behavior as Problem Solving

There are three broad components of information seeking (p. 402);^[57] information need, search strategy, and execution of strategy. Search behavior is redefined as “a problem-solving activity in which subskills are organized and retrieved according to the individual’s perception of a current information need” (p. 403).^[57] conducting a search is a broader unit within which are embedded hierarchical subskills, one of which might be the strategy of using periodical indexes. Similarly, this subskill has other organized subskills within it, such as deciding on search terms, selecting the right index, looking up the subject in the index with the most current date first, and so forth. Each subskill is itself composed of other hierarchically organized skills. Search behavior is thus “goal-directed problem solving” (p. 403).^[57] User-centered instruction takes this into account: “Library use is an activity of one mind seeking contact with other minds. The study of the cognitive processes of library users allows librarians to develop a new focus on the inner microenvironment of information seekers” (p. 407).^[57]

Indexing is the language chosen by information specialists to reflect the “about-ness” or content of documents. “User-centered indexing,” according to Fidel (p. 572),^[58] “cannot be developed before searching behavior is understood better.” A number of issues that guide the practice of indexers are related to users. One is the issue of user language; that is, the level and specificity of the index terms. Another is the exhaustiveness or comprehensiveness (i.e., what to cover and what to leave out). In the older paradigm, also known as “the document-oriented approach” (p. 573),^[58] “indexing can be done with no knowledge or consideration of users or their needs,” but in the new paradigm, “request-oriented indexing” acknowledges the centrality of users. One example cited

by Fidel is a study in which a “filtering” technique is employed to check each descriptor chosen by the indexer: “Would any one of our users who is interested in the content of this document use this descriptor as part of the query formulation?” (p. 574).^[58] Request-oriented indexing depends on the indexer’s ability to anticipate user requests. Each document is represented in the database by a list of anticipated requests, and these elements form the index language.

Automated indexing has grown in the past thirty years, and its developers claim that retrieval performance is at least as good as systems that use intellectual indexing (p. 575).^[58] Several reasons are given in favor of the user-friendliness of automated indexing. One is that search requests expressed in natural language are accepted and Boolean query formulation is not required. A second advantage cited is the provision for relevance feedback based on user ratings of retrievals and how these can improve the search. Other advantages mentioned are ranked output of retrievals in terms of relevance and the capability of automatic query expansion. Thus, on the one hand, automated indexing provides advantages in flexibility, dynamism, and control. On the other hand, its terms are limited to the language of the text itself, as no descriptors or keywords are employed.

An experimental study attempted to implement a user-responsive search system that allowed people to “add keywords to the indexing of an online retrieval system based on their use of the documents in the system” (p. 153).^[59] A dynamic system that adapts to the needs of users is indeed a user-centered feature, although we still lack the practical knowledge for implementing such a system. In this case, the system had difficulty dealing with user language and error control. Variant spellings, errors in spelling, and terms that are too broad need more complex expert systems than are now routinely available. In an attempt to remedy this insufficiency, Denning and Smith^[7] tested ELSA, an intermediary system that features the capability of “intelligent search functions” that solve some of the problems associated with user spelling and language. For example, when users are not familiar with the syntax of a system, they may type in “Search James, William” which does not work, as the system expects “aut/James, William.” ELSA helps with this problem by accepting variant forms for author searches and by making lists of available concepts as well as lists containing synonyms that trigger available concepts.

There has always been the recognition among indexers that indexing and searching are related, but now the powerful tools of automation are providing new user-centered capabilities. The trend is not to choose one system over another, but to make all systems available simultaneously in the service of accommodating user styles, needs, and backgrounds. This is especially desirable because there is “little agreement in the names people use and the names recommended for use by LC [Library of Congress Subject

Headings], implying that retrieval systems should do more to accommodate common naming behavior” (p. 116).^[60]

Types of Moves in Searching

To understand the user’s perspective, Fidel^[61–63] has studied how users make decisions by observing their “moves” within a search activity. Examples of moves made by searchers include any activity that allows them to continue progressing, such as the following:

- Using help files
- Reading the screen
- Issuing commands
- Guessing
- Rereading the screen
- Asking questions of themselves or others
- Consulting documentation
- Trying to get to a menu
- Trying to get out of a menu
- Trying to figure out where they are
- Modifying a search string
- Displaying a record

Fidel has studied several aspects of online searching behavior, including (1) choosing databases, (2) choosing search terms; (3) conducting the search, (4) reviewing results (feedback review), (5) making new decisions in response to the evaluation of results, and (6) terminating the search and getting a printout.^[61–63] Her approach consists in identifying incidents in which a search key was selected, and then fitting each incident into a decision tree, resulting in a catalog of criteria for decisions. For instance, during the process of choosing search terms, the first decision point is to determine whether a “single-meaning term” (which is good for free-text searching) is wanted or a “common term (broad and fuzzy meaning with too many contextual variations)” (p. 493).^[61] In case it is a single-meaning term, the next decision point is to map the term to a descriptor. For example, the topic “Anxiety about using computers” is matched to descriptors such as **TECHNOPHOBIA** (narrower) or **ANXIETY** (broader). This matching process involves a semantic content (or the concept) and the system language (controlled vocabulary). If no exact match is found, then a partial match may work in conjunction with text words (key terms) for an inclusive search. If no match is found, text words can be used to probe indexing further. This case-history approach demonstrates that searchers use intuitive as well as explicit “rules” for decisions.

Descriptive efforts on how users make decisions in an information retrieval situation produce knowledge engineering trees that can help in the design of intermediary

systems that assist the searcher through “dialog box” inquirers about the user’s purpose and scope of the search as well as requesting evaluation of sample retrievals. According to Fidel

Understanding how searchers of all types look for information, and how they interact with existing systems, can provide guidelines for searchers’ training and assistance (p. 501).^[62]

It is evident that decisions during searching are guided by users’ *perceptions*. These can be identified by asking them to state the reason for a particular decision. These reasons or perceptions can often be validated by objectively observable evidence such as transaction logs that record what keys have actually been pressed in sequence. Another method of validation consists in examining frequency distributions and correlations across several searchers for a single search, or across several searches for one individual. Other variations include the number of databases, different subject areas, type of information venue (research, industry, other), and the number of moves required (task complexity). Having conducted research with these variations, in her conclusions Fidel emphasizes the finding that search decisions and strategy are heavily determined by system features, especially the structure of controlled vocabulary and the availability of effective online thesauri.

Thus, research should be carried out to discover which features of databases and their thesauri can be standardized without affecting retrieval quality. The role of intermediary expert systems will then be to bridge the necessary differences, employing switching languages and other terminological and semantic networks (p. 514).^[62]

Fidel analyzed the verbal and search protocols of forty-seven professionals in the hope of discovering “what characteristics of searching behavior constitute a searching style” and “in what way one individual searcher is different from another, all external conditions being equal” (p. 515).^[63] Fidel, citing Fenichel,^[64] estimates that research on online search behavior has declined recently because prior experiments have failed to provide conclusive results on such individual differences as experience, cognitive attributes,^[65] personality traits,^[66] and type of request.^[67]

A common explanation given for these partly negative results is that “individual search styles override most measured attributes of searching behavior” (p. 515).^[63] Fidel thinks that this attitude is premature because we do not yet understand the specifics of search styles. She analyzed data on verbal protocols of thought processes, both while searching and from interviews with searchers to determine reasons for their search key selections. Fidel built a

two-layered model to represent the derivation of six types of moves. A move is defined as any modification in search strategy aimed at improving results. Operational moves do not change the meaning of a request, whereas conceptual moves do. For instance, type 2 moves are operational moves aimed at increasing precision. Other examples of moves include the following:

Type 1

- Intersect free-text terms to occur in a predetermined field
- Limit time (by date)

Type 3

- Add synonyms and variant spellings
- Eliminate restrictions previously imposed

Type 4

- Intersect a set with a set representing another query component
- Select a narrower concept

Type 6

- Enter a broader descriptor or term
- Group together search terms to broaden the meaning of a set

Of the 1244 moves made by the forty-seven professionals in their 281 searches, 60 percent were operational and 40 percent were conceptual. The number of moves to increase recall was about double the number of moves to increase precision. Fidel takes this as a sign of “the difficulty in achieving satisfactory recall in the databases currently available” (p. 518).^[63] Operational moves are used to improve precision or to reduce a set, whereas conceptual moves are used to improve both precision and recall. The average number of moves per search was five, with a range of one to eighteen. It is of interest that these professional searchers only used 25 percent of the available moves, indicating that “search systems should remind searchers of the complete array of moves possible in online searching” (p. 519).^[63] Interactivity (number of moves) was not related to purpose, concern with recall, or subject area. It thus appears to be an element of search style.

In conclusion, Fidel uncovered three search style characteristics of professionals that were not related to results or success.

1. Level of interaction or number of moves
2. Preference for operational versus conceptual moves
3. Preference for using text words versus descriptors

Nahl believes that these search style measures can be influenced by the speech act content of instructions, as well as by other searcher characteristics such as success,

satisfaction, self-confidence, and frustration.^[20] Because both the cognitive and affective domains of the user’s world must be addressed, it is clear that the new user-centered perspective needs to focus on a broader spectrum of the user’s involvement in the search process.

Reformulations

According to Dalrymple, “the user-centered approach derives its questions and methodology from the behavioral sciences” (p. 272).^[68] In her study, subjects were assigned search problems, and their cognitive processes were studied by having them think aloud while searching. Of special interest were the “reformulations,” an expression that refers to the attempt to refine the terms of a query.

Reformulations are assumed to be cognitive processes that interact with searchers’ long-term memory retrieval operations and may be conceptually similar to database access and retrieval operations. “Presearch reformulations” transform the language of the information need into terminology that initiates the search. “Search reformulations” are modifications of search terms during the search. For example, the statement, “I’m looking for books about women writers in twentieth century German literature” needs to be translated into the form, “Feminist writers.” This presearch reformulation may be modified later during the search by adding, “Feminist writers German literature.” Dalrymple found that a significantly greater number of reformulations were made when subjects searched an online catalog as opposed to a card catalog. She calls for additional investigations on reformulation to determine whether or not it can be taught, how it is affected by the urgency of the information need or by individual differences in search style, and whether or not it functions as a request for feedback from the system.

Transaction-Log Analysis

The need to study more closely the cognitive processes of searchers was aided by software capabilities that permit a detailed approach to the study of online search behavior known as transaction-log analysis. The authors of a “manifesto regarding the future of transaction log analysis,” Sandore and colleagues,^[69] urge the development of unobtrusive measures for expanding the information base librarians have about users’ style and pattern of information seeking, including searching, browsing habits, circulation activities, and evaluating and digesting information. Such expanded “tracking” will allow the resolution of the fundamental question “whether it is the system or the user that requires improvements” (p. 106).^[69] The authors suggest that

It is possible to conceive of an IR system that was so adaptable that it could make searches successful when

conducted by someone with a totally misguided mental model of the search process. If we design systems that are “idiot proof,” are we encouraging mediocrity by not attempting to educate users with feedback from their searching mistakes (p. 106)^[69]?

These researchers advocate helping users become proficient searchers, and to accomplish this, one needs a research program using transaction-log analysis to advance the knowledge base that information professionals have available about users. Transaction-log analysis “provides a glimpse of the world of user searching that is otherwise inaccessible” (p. 106).^[69] The sequence of cognitive activity is captured in the verbatim record of keystrokes of a searcher, representing decisions made throughout the search. Common strategies, varieties of errors, predominant search modes, and the like are revealed, providing heretofore unavailable information on how users adapt to the system.

User-centered design in the 1990s dovetails with the area of human-computer interaction (HCI), incorporating cognitive engineering, software engineering, and usability engineering, including artificial intelligence (AI).^[70] There is a new awareness and concern about the need to “overcome the gulf that exists between system designers and users” (p. 438).^[70] There is a new desire to deal with users’ psychological blocks and frustrations by building systems that accommodate the various levels of skills and try to eliminate unnatural human-computer exchanges such as having to wait for the execution of a command without knowing how long it will take or even if it is processing the command. Currently, more information-retrieval software designers are providing transaction-log utilities that can aid in studying the local use of systems. Transaction logs do not capture the thoughts and feelings of searchers and thus cannot provide insight as to why search decisions were made. To achieve a fuller description of an individual’s search process, a complementary methodology is required to supplement the transaction-log data.

The Affective-Cognitive Connection

The desire to assist novice users in learning to operate unfamiliar information systems has naturally focused on what knowledge needs to be imparted to allow users to become independent explorers. However, working with novices within an educational setting made it clear to several researchers^[19,56,60,71,72] that dealing with cognitive issues is not sufficient. The affective domain in learning is equally important and possibly more fundamental. Without the desire and continuous motivation to learn, few novices would become independent searchers and cyberspace navigators. There is a significant dimension of *resistance* to information seeking that reflects feelings of technophobia, information shock, and depression

commonly experienced by novices within a bewilderingly complex information world.

There has been a lack of integration of cognitive and affective functions in the user as illustrated in an experimental study on 120 sixth graders comparing their recall scores on entries from Compton’s Multimedia Encyclopedia on CD-ROM.^[73] The research question was whether multimedia presentations were more effective than simple text on screen. No significant main effects were found, and the authors conclude that “it is not sufficient to add animation to text in order automatically to enhance children’s learning” (p. 527).^[73] Although this conclusion is qualified in some ways, it appears that the system’s assessment is based on the children’s performance on cognitive skills alone (recall and inference). The authors report that “reactions to the CD-ROM were almost uniformly very positive” and that students “found the animation sequences appealing,” but still conclude that “its effectiveness as a means to improved learning is dependent on a number of factors such as text, text type, and media integration” (p. 527).^[73] It is clear that the affective aspect is given no weight in the assessment of improved *learning*. The tendency to use comprehension measures without integrating them with affective measures is a characteristic feature of user studies in the older paradigm.

The following is an example of an experimental study that does not integrate the affective and the cognitive domains, but gives equal weight to them in systematic contrasts and evaluation. Seventy graduate students in LIS were introduced to HyperLynx, a hypertext bibliographic information retrieval system.^[74] They were given five search queries, one of which was “to find documents that discuss information retrieval effectiveness.” Search success varied with the query; some were more difficult than others. In the cognitive domain, knowledge of hypertext systems was assessed in interviews, and it was found that this variable had no effect on ability to search or success. In fact, the knowledge differential was small because few students had more than a slight reading knowledge of what hypertext is. In the affective domain, users were asked to compare the hypertext system with the Boolean-based systems they had experienced previously. There was generally favorable response to the hypertext system by the majority, but at the same time, all subjects expressed frustration at not being able to use Boolean searching with the full-text documents. It is concluded that user “preference for string searching for particular search tasks such as authors and very specific content suggests the need for a hybrid system with both string and hypertext search capabilities” (p. 27).^[74] In this study the cognitive and the affective domains were equally addressed, to the greater benefit of users as they struggle to operate in fluid information environments.

An explicit attempt to integrate the affective and cognitive domains of information behavior is found in a study

by Metoyer-Duran (p. 320).^[75] She was interested in how information in a community is diffused by “information gatekeepers,” or “persons who help individuals gain access to resources needed to solve problems.” Information providers and librarians are information gatekeepers by profession, but many people in a community act as agents of information diffusion, for example, housewives who attempt to alter the family’s eating habits and present them with a new dietary philosophy for which they rely on new information. She presents a taxonomic framework with three interacting domains: (1) *cognitive skills*, specifying the conceptual knowledge needed for information literacy, including terminology and logical reasoning strategy; (2) *technological skills*, referring to the operational literacy of information systems and data structures; and (3) *affective skills*, referring to the gatekeeper’s “innovation diffusion and learning behavior” (p. 332),^[75] including resisting or impeding the flow of information or absorbing information selectively and distributing it to others.

The importance of connecting affective and cognitive functions is well known in theory, although considered difficult to apply in practice. Two comments by psychologists illustrate this emphasis: the first goes back to the first modern behaviorist (i.e., after Descartes) and the second is a current research report sponsored by the Air Force Human Resources Lab.

Man has two faculties; will and understanding. When the understanding is governed by the will they together constitute one mind, and thus one life, for then what the man wills and does he also thinks and intends (no. 35).^[76]

These two parts, the will and the understanding, are most distinct from each other, and for this reason, as before said, the human brain is divided into two parts, called hemispheres. To its left hemisphere pertain the intellectual faculties, and to the right those of the will (nos. 45 and 644).^[76]

All activities are changes of state and variations of form, and the latter are from the former. By state in man his love is meant, and by changes of state the affections of love; by form in man his intelligence is meant, and by variations of form his thoughts; and thoughts are from affections (no. 1146).^[77]

It is simply not possible to design either cognitive or psychomotor instruction without including some affective component. The very act of establishing an instructional goal implies some value to the person, organization, or society in its achievement. The motivation to learn may already exist in the student before instruction, or it may need to be generated or enhanced by the instructional program. It is precisely because the affective is so entwined with the cognitive and psychomotor learning achievements that it needs careful attention during the design and development of instruction (p. 18).^[78]

The ACS information unit

In the field of LIS, Kuhlthau has consistently called attention to the neglect of the affective domain.

While information seeking is recognized as a cognitive process, the affective process is rarely considered as interacting with the cognitive as part of a whole experience. Incorporation of the affective . . . is essential for fully understanding the experience of information seeking, but it has not yet occurred on any significant scale. . . . There is much we do not know about how individuals construe and reconstrue during information seeking. These studies do indicate, however, that the process is not purely cognitive. Feelings of anxiety are prevalent early in the search, and levels of confidence increase considerably during the process. . . . While it may not be necessary to dwell on feelings in information-seeking situations, it is necessary to incorporate an awareness of affect into our professional construct of information seeking. Until the triad of thinking, feeling, and acting is fully accepted as the nature of information seeking, mediation [i.e., instructional intervention] is likely to be fragmented and limited (pp. 112, 117, and 127).^[72]

Kuhlthau astutely points to the need for information professionals to become more systematic and more holistic in their approach to instructing users by addressing affective and cognitive domains.

To this must be added attention to the sensorimotor domain of hand-eye coordination and action. In an effort to express this connectivity of function among the three behavioral domains, a three-dimensional model of learning information structure was proposed by Jakobovits and Nahl-Jakobovits^[79] emphasizing the principle that every information skill from the smallest to the most general is constructed from affective, cognitive, and sensorimotor behaviors acting together as a unit within a hierarchical behavioral system.

The instructional significance of the Affective Cognitive Sensorimotor (ACS) information unit is that teaching people to become searchers, or helping searchers to be better searchers, involves the management of three different types of human memory— affective, cognitive, and sensorimotor. Affective memory is required for acquiring affective information skills, just as cognitive memory is required for learning cognitive information skills. The same is true for sensorimotor memory. Advances in research and practice will reveal the characteristics of each memory and how these may be applied to curriculum design (p. 460).^[79]

The suggestion that information teaching and services adopt a behaviorally integrated design broadens and deepens the user-centered consciousness of information professionals because it involves a holistic orientation toward users. *Holistic user-centeredness* provides “a

unifying framework for preparing curricula in any subject” and “represents a shift from impressionistic instruction that is based on expert knowledge alone to an approach based on both formal analysis of learner needs and expert knowledge” (p. 74).^[80] The permanence of the user-centered revolution may depend on productive research and development of a comprehensive theory of user behavior in the information environment.

Longitudinal Study of Information Seekers

In a series of studies on information seeking from the user’s perspective, Kuhlthau^[81] explored the cognitive and affective aspects of users’ experiences in information-seeking situations. She points to a gap between how searchers think and feel, on the one hand, and how information providers think and organize information on the other. At one end of the spectrum, the system’s pattern is based on certainty and order; at the other, the user’s pattern is based on uncertainty and confusion. Thus, information has a mechanistic as well as a human dimension. Users assimilate information from various sources and transform it into meaning by constructing a personal point of view and creating new knowledge that is sharable with others (p. 361).^[81] Her review of the research on information seeking from the user’s perspective includes the following highlights:

1. Most studies conducted in the past are from the perspective of the system.^[82]
2. There is a new interest in moving away from system-oriented research toward a focus on users of information, especially on their problem-solving and decision-making behaviors.^[83]
3. A fresh approach provides a cognitive science point of view that takes into account the user’s thinking processes and evaluations of the information retrieved.^[84]
4. Users interpret information in terms of personal life characteristics and these are likely to be as important as system considerations in information retrieval.^[85,86]
5. To understand how people find and use information, we need to combine their cognitive maps of the searching environment with a model of the system’s design features.^[87]
6. The users’ ability to articulate requests to the information system depends on their levels of understanding their problems. Because their level of awareness of their information need may be initially low, they may have little success in specifying what is needed.^[87]
7. Users’ queries involve at least four levels of awareness of information need: “visceral” (below the threshold of awareness), “conscious” (aware of the need but not yet formulated in specific terms), “formalized” (explicitly

expressed), and “compromised” (translated into the terms of the system).^[88]

Kuhlthau emphasizes that an information search “is a process of construction which involves the whole experience of the person, feelings as well as thoughts and actions” (p. 362).^[81] To put it more specifically,

A model representing the user’s sense-making process of information seeking ought to incorporate three realms of activity: physical, actual actions taken; affective, feelings experienced; and cognitive, thoughts concerned both process and content. . . . While purely cognitive conceptions of information need are adequate for some research purposes, consideration of the affective dimension of users’ problems is necessary to address a wider, holistic view of information use (p. 362).^[81]

Kuhlthau argues for a new “dynamic” perspective on the searcher’s world. An information need becomes “the gap between the user’s knowledge about the problem or topic and what the user needs to know to solve the problem” (p. 362).^[81] She argues her perspective through “personal construct theory,” originated by personality theorist George Kelly.^[89] This cognitive approach describes how new information is assimilated, beginning with “confusion” brought about by “inconsistencies and incompatibilities” between the new information and currently held constructs. Doubting the validity of the information may follow confusion, and experienced threat may lead one to discard the new information. Alternately, users may attempt to incorporate new information by constructing new hypotheses that allow a more inclusive construct system.

Kuhlthau’s focus on longitudinal studies represents an interest in the dynamic evolution of an information-seeking problem within the personality parameters of a user. To obtain data on this private arena of the searcher’s world, Kuhlthau’s subjects kept written records of their feelings, thoughts, and actions about their library research project. They also kept logs in which they recorded the sources they used, the procedures they went through in finding sources, and their evaluation of their usefulness. In addition, they filled out a questionnaire that asked about their perceptions in six areas of library activity: topic selection, research assignments, focus formulation, procedures for gathering information, frequency of library use, and role of mediators. Taped interviews were conducted in which students drew flowcharts describing the process they followed.

With this intensive and longitudinal data on twenty college students, Kuhlthau developed a six-stage model of the research process. The model was verified with 385 college students at eleven universities with three temporal data points; initiation of the research assignment, its mid-point, and its closure. Her observations draw an affective progression in the search process, from initial states of

uncertainty with vagueness to later stages of optimism, confidence, and satisfaction with more narrowed, focused, and synthesized information (p. 367).^[81] Kuhlthau notes three broad psychological effects; (1) interest in a topic increases as a search progresses; (2) the topic changes as information is gathered; and (3) a central theme evolves as information is gathered. Her conclusion on the importance of the affective component is explicit.

By neglecting to address affective aspects, information specialists are overlooking one of the main elements driving information use (p. 370).^[81]

The primacy of affect has been known in education and psychology, and only recently has come under consideration in information environments.

The Taxonomic Model

The taxonomic model has been applied by Metoyer-Duran to form three-dimensional profiles to idealized types of information gatekeepers;^[75] for example the “broker profile,” the “information professional profile,” or the “unaffiliated gatekeeper profile.” This last refers to individuals who think of themselves as ordinary people rather than innovators, yet they respond out of “personal conscience, or a sense of social obligation, to community members who turn to them for information or referral to help resolve basic problems” (p. 336).^[75] The information behaviors that occur within the unaffiliated profile are ranked at a low level in all three information domains in comparison to the professional profile. In the affective domain, information professionals and managers have a facilitating function, whereas conservative community members are seen as having an impeding function because they tend to express opposition to innovation. Metoyer-Duran’s analysis is of interest to the user-centered paradigm because it encourages a view of information-seeking behavior as culturally influenced and interprets it within a social and communicative perspective.

Another attempt at integrating the cognitive and affective domains of users is the taxonomic approach to information-seeking behavior representing Nahl’s research.^[20,71,79,90] The level of integration of the three behavioral domains may be seen in the following example (p. 75):^[80]

These three behavioral domains are interdependent, so that every *affective* behavior is accompanied by related *cognitive* and *sensorimotor* behavior. For example, a student who gets an assignment from a professor suddenly has a new *goal*; to get the assignment done by the due date. Then the student must cognitively *plan* how to accomplish it. And finally *execute* the required steps. Within this global process, many sub-goals and intermediate plans and acts occur. For example, “Search PsycLIT

for journal articles on the topic” is a sub-goal. Within this, there are sub-sub-goals of selecting search terms, planning search statements, and entering them on the keyboard.

This approach contrasts with the profile model used by Metoyer-Duran,^[75] primarily in the specificity with which the information behaviors are identified. The affective-cognitive integration needs to be applied at both the general level (as in Metoyer-Duran^[75] and the microdescriptive level, as in the following illustrations (p. 7).^[91]

1. In the *affective* domain; feeling excitement at a discovery; experiencing stress from doubt; being disappointed after a search; persisting in an effort; taking care to be thorough; being pleased with a quotation; sticking to a plan; overcoming technophobia
2. In the *cognitive* domain; devising a search protocol; deciding to retain a title; summarizing an article; noting a connection; evaluating relevance; rank-ordered preferences; thinking of a productive keyword; using correct command statements
3. In the *sensorimotor* domain; walking to locations; discriminating between symbols; hand-eye coordination; taking notes; noticing presence or absence; copying precisely; operating a terminal; following a map; alphabetizing; following range numbers and guide words; finding information on screen displays

An integrated approach in the user-centered paradigm involves all three behavioral domains at the general and specific levels.

The Novice Searcher’s World

The taxonomic cataloging of user behaviors in information environments, also referred to as the “matrix approach,”^[92] promotes the user-centered paradigm by facilitating the identification of skills and errors that populate the searcher’s world. In a detailed study of some of the psychological factors that are presented in the searcher’s dynamic world^[19,20] seven environmental layers were identified. Fig. 1 illustrates the complex information retrieval environment of the novice; first, the *search query*, which provides an overall context because it is the ultimate goal that motivates the beginning and end of a search effort; second, the *subject headings* and indexes, which limit the universe of searchable topics; third, the *search software*, which imposes particular requirements for operation; fourth, the *point-of-use instructions* and online help, which provide suggestions and examples to facilitate problem solving or troubleshooting; fifth, the *sensorimotor* environment, which determines how users interact with the screen and the keyboard; sixth, the *cognitive* environment of users’ reasoning processes and the formulation of search strategies;

Fig. 1 The searcher's dynamic world.

and seventh, the central *affective* environment populated by users' emotions and motives.

These seven environmental layers envelop searchers and create a dynamic world that the user-centered approach needs to address, individually as well as globally. For example, an attempt was made to address the affective and cognitive environment of searchers through point-of-use instructions that were specifically written to anticipate common problems experienced by novice searchers using a CD-ROM database.^[20] As a guide to developing the language of the instructions, an affective taxonomy was used that lists instructional speech acts at three levels. First, the *orienting* level is intended "to reduce anger and maintain reality check"; for example, "telling what is reasonable to expect" affects whether a searcher is being realistic or is disappointed, and "telling how long it takes (seconds or minutes)" helps alleviate impatience due to unfamiliarity. Second, the *advising* level "counteracts anxiety and builds positive attitudes"; for example, "giving feedback (what will happen if...)" helps alleviate anxiety and builds confidence, and "rank-ordering options or strategies" reduces fear of failure and builds feelings of trust. Third, the *reassuring* level is

intended "to overcome resistance and encourage acceptance"; for example, "affirming principle that users are never at fault" eases acceptance by reducing resistance, and "reinforcing user's perceived self-efficacy" helps users overcome feelings of helplessness and leaves them feeling empowered. Taking care to orient, advise, and reassure novice users helps reduce the psychological cost or operating in challenging information environments.

Affective Management Principles

Other features of the information environment have been identified in support of the affective needs of users. In one study, four principles are stated. First, *affective knowing* asserts that "a procedure is not fully understood until it is performed for some desired goal" (p. 25).^[56] In other words, users learn most when given the freedom to practice searching for topics in which they have some interest. Second, *social facilitation* refers to the strengthening of motivation and persistence when the search is performed jointly with a peer or within a small group. Third, *affective feedback* calls for "manifesting the affective reactions of individuals to themselves" through an attitude scale that

visibly shows where the raters are in relation to their own ideal. This activity “clarifies for them the distance they need to cover to master target skills” (p. 27).^[56] Another method is to help learners correct their errors in feedback sessions to facilitate their continuous striving for improvement. Fourth, *validation* is the process of orienting, advising, and reassuring users so that they can more easily cope with the challenges of the information environment.

Questioning Behavior of Novice Searchers

In the information retrieval literature, user questions are considered to be equivalent to topical information needs or research queries.^[3,93,94] However, the search process plunges users into another parallel domain of information needs (i.e., they need information about searching itself): “The basic underlying assumptions. . . are that question generation arises from an information need and that questioning is a behavioral act to satisfy that need” (p. 95).^[86]

An interesting finding about the needs of searchers was reported by Nahl and Tenopir^[90] who tape-recorded and analyzed every question that seven novice searchers asked a human monitor during five one-hour sessions while searching a full-text database for information on their own topics. More than 1000 questions were asked at an average of one per minute. One-third of these user questions were in the category *seeking confirmation*, defined as a question that contains the answer, so that the monitor always responds affirmatively (e.g., “Is it 3 comma k?” or “So now I want to combine both of them?”). In other words, searchers knew the answers but needed confirmation in order to proceed comfortably. As the authors point out,

From a system-centered point of view it might appear that seeking confirmation questions are superfluous, since no new cognitive information is provided. However, from a user-centered view-point it is assumed that confirmation questions are essential to help searchers persevere instead of quitting prematurely. Searchers need continuous motivation to keep postponing quitting. Confirmation seeking is simply a method for providing searchers with this continuous motivation. It is thus affectively essential, even if cognitively superfluous (p. 282).^[90]

Other types of questions included *formatting input* (e.g., “So what do I press?” or “Do I have to leave a space?”), *search strategy* (e.g., “Is this something I’d want to truncate?” or “What if I just want a picture and this database doesn’t have pictures?”) and *personal chat* (e.g., “Do most people try to keep up with reading all of the [full text]?” or “Can you imagine a bookless library?”). The authors point out that

Some affective system functions now exist in the form of confirmation requests presented by the system after a

command is given, e.g., after issuing a quit application command, the system may present a question. “Really quit? No [Yes].” Others include notifying searchers of what the system is doing during processing time, e.g., “Searching . . .” and “Please be patient, this takes awhile” and “I’m reversing the order of your search terms for a faster search”; and warnings about the possible negative consequences of a search act, e.g., “EDUCATION is a long search” (p. 285).^[90]

In this study, users spontaneously asked a long series of questions throughout their searches that pertained to many aspects of navigating in the system environment. The importance of feelings in the search process became evident when the transcripts of the search session were analyzed.

The analysis of these naturally occurring questions reveals not only the reasoning process of these novice searchers but also the dynamics of feelings, which indexes the users’ hesitations, desire for confirmation, avoidances, fears, and the like. These interact with the user’s knowledge and reasoning to determine the outcome of their external actions. For example, novices sometimes quit a search prematurely without obtaining needed information, when it is easily obtainable through a simple modification in strategy. The present data reveal that *information need* is not unitary: instead, there exists a stream of hierarchically organized information needs (p. 281).^[90]

Affectively oriented questions primarily dealt with the users’ need for continuing motivation to carry out their intentions in the moment-by-moment decision making that constitutes a search. If this motivation wanes, users terminate searches. The human monitor’s response provided the reassurance that searchers were interpreting the situation correctly and performing the right move. *Cognitively oriented questions* dealt with the users’ need to understand results and select search steps. Sensorimotor questions dealt primarily with the users’ need to format input with the correct search syntax and grammar. In both cases, the monitor’s answers supplied the missing information to enable searchers to progress. Nahl and Tenopir call for the development of “affectively oriented system functions” that are more responsive to users in the area of their greatest needs. An awareness of this principle may already be observed in many systems for novice end users, such as the following:

- Providing an option for confirmation request (e.g., “Really quit? No [Yes]”, or “Delete file xx N [Y]”)
- Notifying searchers of what the system is doing during processing time (e.g., “Searching . . .” or “Connecting . . . Waiting for reply . . . Transferring data . . . 23K out of 35K read . . . 12 secs. remaining”)
- Warning about the possible consequences of a search act (e.g., “HISTORY is a long search! DO you wish to specify further?”)

As research on users accumulates, a professional knowledge base will be developed for understanding and serving people's information needs.

Providing a user-centered environment requires an understanding of how users learn and acquire proficiency in information seeking. Three factors have been identified from learning theory that ensure the orderly acquisition of affective, cognitive, and sensorimotor skills, namely, "sufficient motivation, active responding, and reinforcement."^[55] According to this view, information seeking is a complex behavior that is acquired to some extent through the laws of conditioning. Good decisions are automatically reinforced because they lead to positive outcomes. Thus, the sequence of actions that led to the results is strengthened (i.e., it has been added to the learner's repertoire of search behavior skills and is therefore more likely to be repeated as a habit). Positive consequences improve skills, whereas failures weaken the behavior. The information environment needs to address user failure: "The remedy for negative consequences in online searching is to have workable alternatives to continue the search in a new direction. Bibliographic Instruction (BI) can facilitate this by teaching users how to respond to system error messages, too few or too many 'hits,' and other searching problems" (p. 77).^[55]

Uncertainty and Zones of Intervention

As discussed previously, the importance of the affective information environment is fully recognized and addressed in the work of Kuhlthau (p. 187),^[72] who recommends the counseling approach to library services.

The mission of the 1980s was to automate and to network library and information services. Access has been dramatically expanded by automation, networking collections, and databases. Operations for providing information and resources have been streamlined by technological applications. While automating and networking continue to be a priority, the mission of the 1990s, and beyond, calls for services that promote the understanding of ever-increasing amounts of information. A mission of library and information services of the 1990s is to counsel people in the use of resources and information for learning, working, and living. It is no longer sufficient for library and information services merely to provide resources and to offer assistance in the location of materials and information. In the technological age, people require services that counsel them in understanding information and guide them in the process of seeking meaning.

Kuhlthau's central thesis is that vast information pools coupled with rapid technological change engenders unpredictability: "Uncertainty is pervasive in the seemingly certain technological environment. The confrontation between the uncertain person and the certain system requires professional intervention. There is a critical need

for professional counseling in seeking meaning and understanding information" (p. 187).^[72] As pointed out by Morris (p. 230),^[49] Kuhlthau's method is close to Dervin's sense-making approach reviewed above in viewing information seeking as the construction of personal meaning. Cognitive enrichment is preceded by affective uncertainty and followed by affective satisfaction.

Relying on the writings of George Kelly, Jerome Bruner, and S. Vygotsky, Kuhlthau attempts to locate the information search activity within the basic personality structure of the individual. Although Kuhlthau does not use the following specific descriptions, her approach is consistent with this type of behavioral model.

The affective domain drives the information search process through one's awareness of an information need. A person is "driven" to seek answers, and when information is perceived as personally relevant, it is seized upon by the cognitive domain and thus acquired as one's own. The person is now changed because different thoughts and feelings occur. One's conclusions are different (or reconfirmed and strengthened) and one's outlook or mood has changed. This process of personality involvement with new information includes certain feelings and thoughts that are common or universal as psychological processes. These include feelings of uncertainty, confused thoughts, resistance to new information, anxiety, and depression. Individual differences exist in how intense or enduring these processes are, and how well the individual is equipped to cope with challenge and stress.

Kuhlthau recommends various strategies for implementing "a process approach" to information counseling. One important step at the beginning is to help users become aware of the stages of information seeking, especially the reality of uncertainty, confusion, stress, and discouragement. The strategy of "charting" helps users visualize the entire research process, thus making expectations more objective. Seeking meaning is a "constructive process," and ignorance of this process frequently limits the choices people make. This fits with the idea that helplessness is a learned habit, or that self-efficacy beliefs are based on habitual modes of explanations in one's thinking and coping strategies. Kuhlthau emphasizes the importance of "conversing" or discussing with users their research steps throughout the process and not just during an initial consultation period.

Kuhlthau's proposals reinforce Nahl's description of the novice searcher's world as dynamic in both the affective and cognitive domains of behavior. An information need creates a gap between what the user knows and what information is needed to solve a problem,^[96] and as the information-gathering process unfolds, the user's state of mind changes, cognitively and affectively. It is a unique experience in which "the choices along the way are dependent on personal constructs rather than on one universal predictable search for everyone" (p. 9).^[72] To be valid, user-centered approaches must allow for individualization.

Self-Witnessing Methodology

Nahl's taxonomic model, especially its structural integration of levels and domains of user behaviors, is compatible with Dervin's sense-making theory and Kuhlthau's counseling approach to the information search process. These three orientations converge on placing the user at the center and employing scientific techniques for discovering the details of the user's live experience in the information environment. Self-witnessing methodology emerges as a common tool serving objectivity, empiricism, and a theoretical framework, even if still in development. There are three basic characteristics to this behavioral methodology; concurrent self-reports, authentic self-descriptions, and integrated probing.

Concurrent self-reports

A major problem with system-centered "user-centeredness" is that it is insufficiently objective, despite the use of summative rating scales and survey data. It uses categories of measurements intuitively selected by the experimenter in order to obtain global, summarative, and *retrospective* judgments from users. In a major scholarly effort, Ericsson and Simon^[97] fully establish the superiority of *concurrent* reports obtained throughout the time user activity and experience are occurring. *Protocol analysis* involves tape-recording users saying aloud the thoughts and feelings they experience during the task, transcribing the audio, and analyzing it to reveal thought sequences, decisions points, intentions, and reactions. The categories that emerge from such analysis are thoroughly user-grounded, with minimal imposition by the experimenter. They are objective because users are the only source of data for their thoughts, reasons, and perceptions. Reporting on such data as they occur is a natural process of language activity and does not depend on special abilities or training, as illustrated in another major study.^[98]

Authentic self-descriptions

Two reasons may be stated why self-witnessing data are more authentic and useful than data based on summative rating scales or surveys. First, they use natural language expressions, which are more accurate and specific. Second, they are spontaneous responses to the ongoing mental activity and state. However, intermittent probing by the experimenter is necessary in order to ensure relevance and completeness of information obtained.

Integrated probing

Research on the self-witnessing method^[24,97–99] indicates that although the user's self-reports are spontaneous and natural, they are incomplete unless the experimenter

provides adequate prompts. What constitutes adequacy in prompting varies with the theoretical justification of the study. In the taxonomic approach, probes are defined by level and domain, especially the latter. For instance, cognitive prompts elicit rationales for decisions, whereas affective prompts call forth motives and intentions that seek fulfillment from cognitive rationales through sensorimotor executions.

User-Based Behavioral Objectives for Bibliographic Instruction

Within the bibliographic instruction field, the most recent version of the model formulated by the profession is user-oriented in its purpose, attempting to incorporate and "outline the pertinent processes individuals use when gathering information" (p. 257).^[100] However, the model statement of educational objectives for user instruction remains at a broad level of description, in the form of general and terminal objectives. From a user-centered perspective, the model statement needs to evolve toward specifying the actual behaviors performed by users during an information-seeking or -processing activity at the level of enabling objectives. The authors of the objectives recommend that instructors select terminal objectives from the model statement and create necessary enabling objectives specific to local needs. A step toward this elaboration was proposed and involves content analysis of user self-reports (or "structured diaries") that describe one's feelings, thoughts, and actions while engaged in searching.

The self-reports of library users provide access to relevant information about their mental processes as they pursue an assignment. We obtained information on inaccurate assumptions and other errors, on skills learned during the assignment, and on how to improve assignment instructions. Self-reports indicate part of what students feel, think, and do in carrying out an assignment. Such information may be helpful in understanding the nature of library users' feelings, thoughts, and actions. It is an advantage to be able to correctly anticipate user behavior and to communicate adequately with users, accommodating our suggestions to their level and pace (p. 6).^[91]

Nahl-Jakobovits and Jakobovits present a "taxonomy of library speech acts" in the affective, cognitive, and sensorimotor domains to help information specialists develop empirical, user-based enabling objectives in the planning of instruction. The deepening of user-centered consciousness is possible when the information skills of the users are defined as "integrated behavioral objectives."

Bibliographic Instructional Design (BID) represents the new paradigm in B1, a shift from a tool-based library instruction approach to an interactive, access-based approach focused on active learning and critical thinking. BID places an emphasis on the needs and behaviors of

information seekers in complex information environments. B1 librarians have accepted the vital role of teaching people how to interact with information systems, how to evaluate output, and how to gain control of the information environments (p. 73).^[80]

The authors propose a taxonomy of terminal objectives for information literacy that is organized in a matrix of three levels and three behavioral domains. Information literacy begins with *critical thinking skills* (level 1), proceeds to *information retrieval skills* (level 2), and matures in *lifelong learning to learn skills* (level 3). Each level includes affective, cognitive, and sensorimotor learning objectives. For example, affective skills at the critical thinking level (A1) involve “becoming sensitive to the need to evaluate information.” Cognitive skills at the information retrieval level (C2) involve “formulating a question and planning a search strategy. Sensorimotor skills at the learning to learn level (S3) involve “facilitating one’s life through lifelong information seeking and enjoying its rich benefits.”^[80] Similarly, using the matrix definition, all nine zones of instructional objectives are defined. Information specialists can use this taxonomy to plan instruction and assistance that is *integrated*, so that the objectives address the affective, the cognitive, and the sensorimotor domains of user behavior.

From the perspective of user-based design or planning of instruction and assistance, objectives are laid out in a synthetic or developmental order; from over-all goals to general objectives, terminal objectives, and enabling behavioral objectives. For example, a decision to provide an Internet connection in an academic library might lead a committee to decide to provide instruction in how to conduct Veronica searches of Gopher menus. This is a *general* objective. A subcommittee might then consult with other experts and draw up a list of terminal objectives that might include navigating menus, formulating queries, applying Boolean operators, and saving documents to users’ disks. The list of *terminal* objectives would then be assigned to instructional staff to work for locating Internet documents through Veronica searches. *Enabling* objectives at the behavioral level normally require demonstrations, supervised search practice, handouts, charts, the user of online help, and other learning activities. Enabling objectives guide instructional procedures and need to be very specific and detailed. For example

General objectives: Teaching new Internet users to conduct Veronica searches and save retrieved documents to their disks

Terminal objectives: Accessing the Gopher menu; accessing the Veronica screen; formulating queries; using Boolean operations; saving a document

Enabling objectives: Locating Gopher; highlighting Gopher indexes; using line numbers on Gopher menus; canceling a request; selecting possible Gopher titles for

various topics of interest; beginning a Veronica search; devising search terms; using Boolean operators; using bookmarks; using the history function; using commands for saving and printing options; inserting and ejecting disks; and so forth.

Note that as we descend the synthetic tree from general to specific, there is a need to include greater detail. However, from the user’s perspective, the order of learning and understanding is exactly reversed. Users begin with an ability to understand at the level of the enabling objectives. How do I get out of this screen? How do I get there directly? Where did I go before this? What’s the save command? These are their immediate problems and their total focus. The solution to a lack of enabling skills is provided at the next level up, where terminal objectives organize individual skills into the ability to execute complex goal-related tasks. At the third level, users begin to acquire self-confidence in their general ability as an information-literate person capable of sitting down at a terminal and figuring out how to search the Internet. Users thus see *analytically* (from frustrating detail to general know-how), whereas instructors see *synthetically* (from general goals to specific objectives).

Research on the modification of users’ behavior with systems highlights the complexity of the user’s involvement in the information environment. Some researchers perceive the need to consider the whole user and have proposed holistic theories to help safeguard user-centered consciousness in the applied world of system design and user access.

Constructing a Scientific Basis for User-Centeredness

The past two decades have brought user-centered consciousness to the fore; the next few years should yield greater theoretical sophistication and efficiency. Theoretical integration with psychology, education, sociology, and communication is already visible. Table 1 is a summary of the work to date of three researchers who have independently evolved a scientific and empirical orientation toward user-centeredness. The list is not meant to be exhaustive, and other researchers could be included whose work and ideas are compatible.^[12,58,94,96,101,102]

Although distinctly different in procedure and disciplinary grounding, the writings of Brenda Dervin, Carol Collier Kuhlthau, and Diane Nahl together encompass a broad section of scientific research and method giving credence to the expectation of a new user-centered paradigm, effective enough to produce a permanent change in how the information world continues to develop.

The three approaches listed in Table 1 taken together cover the entire spectrum of the user’s universe.

Table 1 Dervin, Kuhlthau, and Nahl: Key Concepts of Three Complementary User-Centered Methodologies

The topic		
Dervin’s sense-making Communication Theory	Kuhlthau’s diagnosis—intervention orientation	Nahl’s self-witnessing behavior model
The main question		
How users assimilate information and apply it to their life situation	What stages users go through and how to assist them in the information-seeking process	What users feel, think, and do during an information-seeking session or task
The main answer		
Empowering users by facilitating information transfer within society	Diagnosing user problems and intervening with particular information services at the appropriate stage	Instructing lifelong novices to acquire integrated behavioral self-modification habits
Key concepts		
• Constructivism • Information as clay versus brick • Observer versus user constructs • User-based user categories • Relativistic information framework • Searching filling an information gap • Knowledge as information transfer • Information exchange as a communicative act	• Constructivist personality theory • Searching is seeking meaning • Longitudinal stages in the information search process • Attention to affective and cognitive needs • Overcoming uncertainty and information anxiety • Zones of intervention for information services • Information counseling	• Integrated ACS information unit • Self-witnessing method • Affective micro-information skills • Teaching self-regulatory information speech acts • Modifying self-efficacy beliefs of searchers • Planning user-based behavioral objectives • Lifelong novicehood and information literate novices

Dervin: How users assimilate information in reaction to their life situation

Kuhlthau: What challenges users go through in the information search process and how to assist them in life-long information seeking

Nahl: What users feel, think, and perform during information sessions or tasks.

Dervin’s conceptual basis lies in the mechanisms that tie the social setting to the individual’s mental framework. Information is not so much a fixed resource or product as a social occasion for communicative exchanges between author-producer and user-consumer. Information is what consumers use to alter their life situation. Affective needs reveal cognitive gaps that propel the person to seek, whereupon one seizes what seems relevant and meaningful; that is, what will make a difference in one’s situation. This difference translates into acquiring understanding, changing attitudes, solving problems, constructing interpretations, or becoming more persuasive with friends or employees. Dervin’s descriptions of the information user or consumer make it clear that we are all information seekers and consumers. Being a user or a novice is not a demographic category or personality factor, it is a continuous lifelong process, a state of operating that we all must regularly assume as part of our societal functioning.

Kuhlthau’s conceptual basis is grounded in a psychological maxim. People seek meaning in life, and information seeking is driven by this deep need to make sense out of reality, to attribute causes to events, to hypothesize about what might be. But there is a turmoil associated with

this reality construction because events change or new forces and constraints come into being. With mounting pressure to know, analyze, and decide, one is thrown into states of confusion and uncertainty, sometimes with such intensity that the individual may withdraw or resist further information seeking. The syndromes of technophobia, infoshock, and avoidance can be scientifically studied and cataloged. With knowledge of the stages that users go through, information professionals can provide effective assistance by accurately diagnosing the stage a user is in and intervening with appropriate affective and cognitive facilitation procedures.

Nahl’s taxonomic self-witnessing contributes two basic ideas from behaviorism: first, that thoughts and feelings are behaviors like motor actions; and second, that the three domains (affective, cognitive, sensorimotor) are exhaustive and integrated categories of human behavior. During a search session or activity, users produce a continuous stream of goal-motives, reasonings, and coordinated sensorimotor executions. This stream of behavior is hierarchically organized with goal-feelings directing cognitive sequences that explode into overt decision and action. Behaviors are organized into habits that serve goals and situational demands. They can also be changed by using appropriate behavioral modification techniques such as modeling, imitation, role taking, self-witnessing, instruction, and communication.

User-centered instruction and management needs to view the target behaviors of users guided by bibliographic instruction design that addresses all three domains of human endeavor. Being optimistic about search outcomes

and feeling enthusiasm for one's successes are *affective skills* that can be targeted as behavioral objectives in instruction and measurement. Doubting oneself, avoiding technology, and feeling depressed or overwhelmed in an information crisis are routine affections, cognitions, and acts that respond well to self-modification attempts through self-regulatory speech acts and social support. Higher motives have a controlling influence on lower motives, and users can be given self-witnessing tools to help them become aware of the negative and positive learning contingencies in their information environment. Such tools include inventories of the skills and errors users frequently make in specific situations, along with taxonomic descriptions of information states, stages, and processes.

THE FUTURE OF USER-CENTERED APPROACHES

User-centeredness became visible with policy, was advanced through methodology, and eventuated in a new theory, a new view of the global dimensions that impinge upon users. As policy, user-centeredness continues as an organized affirmative-action-like program attempting to reverse the user-unfriendly atmosphere of the system-centered information environment. This includes the sphere of legislation, planning of services, and the education of professionals. As methodology, user-centeredness has evolved a wide range of measures for user factors in the information equation. Three degrees of shifts have occurred. Nearest to the system-centered orientation are user data obtained through rating forms, survey questionnaires, and interviews. Further along, and closer to users' search activities, are transaction logs, journals or diaries, and longitudinal case histories. Closest to user-centeredness are concurrent think-aloud protocols and directed self-witnessing reports, including rating scales, if used concurrently, about one's actions, thoughts, and feelings throughout the search process.

As theory, user-centeredness has evolved an entirely new range of explanations of what it is like to be users and how to manage their needs. Cognitive science, communication theory, and educational psychology each play visible roles in the development of the user-centered paradigm. The *cognitive science* influence is a source of knowledge for understanding how users think within the information sphere, including how they solve problems, how they make decisions, how they represent systems conceptually to themselves, how they deal with special terminology, and what errors they are prone to make. Influence from *communication theory* continues to evolve a transactional perspective on information as a subjective, creative, or constructivist accomplishment. The information gap that users face with disturbing feelings of uncertainty demands an existential confrontation with oneself and the world of

information. Managing this world for users is unavoidably involving to information professionals, demanding an activist mind-set that pursues, probes, and guides users through various types of interventions.

The influence on user-centered consciousness from *educational psychology* may be seen in the *taxonomic* approach that relies on behaviorism as a means for studying thoughts and feelings in an objectified manner. The matrix approach attempts to identify the simpler components that make up the complex. It relies on two basic concepts known to educators and psychologists, namely, *levels of development* and *domains of behavior*.

User-Centered Principles

Summarizing the trend of the past two decades, the following user-centered principles have emerged.

1. *Counseling interventions.* Information professionals can operate more effectively as information counselors than simply as information providers.

Acknowledging the wholeness and integrity of users as human persons consists of providing affective support within cognitive information transfer.

Understanding users consists of recognizing the common experience of a *predictable cyclic process* feeling challenged, reacting with infoshock and resistance, accepting assistance and redirection, viewing one's progress with satisfaction, and feeling restored and empowered. This up-and-down cycle recurs many times within a search effort, and managing its natural evolution with every user is the routine business of information professionals in the new paradigm.

2. *Role taking.* Information professionals can gain a more developed consciousness of user-centeredness by role taking, or putting themselves in the place of users.

Role taking is a major concept in social psychology and communication. Taking the steps that users go through, coming up against the same barriers users must cope with, overcoming blocks, feeling overwhelmed by too much or too little information—these are useful experiences that may help information professionals tune in to user perceptions. One approach is to search for information that is personally relevant and observe the process from beginning to its resolution, if ever. Information professionals need to be users and searchers on a continuous and lifelong basis. Another approach is to participate in a group exercise of role taking in which one professional assumes the role of user, a second takes the role of the librarian, and the third acts as an observer who provides feedback afterward for a discussion of the interaction. The three then exchange roles.

3. *Discourse management skills.* Information professionals can be more serviceable by acquiring

discourse management skills such as interviewing, negotiating, counseling, and reformulating.

Examples include the use of open questions to avoid premature closure, to personalize the topic, to ask follow-up questions, to identify where the user is in the information search process, and to identify the user's area and level of information need.

4. *Follow-up services.* Information professionals are user-centered when they follow up on user activities in an attempt to establish closure.

Following up on searchers completes the cycle of assistance. It is the recognition that users are real people who need to go through actual steps. Creating a link back to the information professional may be critical to ensure accuracy, success, and satisfaction for users.

A deeper understanding of user-centered consciousness may be gained by applying humanistic principles to the design of the information world. A well-known approach is that of Carl Rogers, a founder of the humanistic psychology movement.^[103,104] A basic tenet of this approach is that humans have an inborn need for *positive regard*, which is to receive sympathy, care, and acceptance from relevant sources. Out of this need to receive positive regard from others, we evolve the need for *positive self-regard*, which manifests itself as holding favorable self-perceptions. A problem arises when the positive regard others give us is constrained by *conditions of worth*. For example, children learn that they can have their parents' love and respect only if they behave in accordance with their parents' wishes. This conditional acceptance helps develop the children's conscience. At the same time, however, it leads to internalization of unfavorable self-assessment. One's perception of self-worth suffers and frequently leads to maladjustment such as alienation, anxiety, denial, and self-blame.

Rogerian therapy attempts to remedy this state of mind by giving clients *unconditional positive regard* so that they might experience positive self-regard even in failure. To reflect this orientation and commitment to the client, Rogers termed the approach "*client-centered therapy*," also referred to as *nondirective therapy* because it encourages clients to solve their own problems within a proper atmosphere. It involves the attempt to understand clients' *internal frame of reference*, which includes their thoughts and feelings in their struggle to cope. If we substitute "searchers" for clients, and "librarians" for therapists, we can summarize the Rogerian form of user-centered instructions in the following five additional principles.

5. *Affective contact.* Information professionals and users must be in affective contact; that is, they must express to each other the relevant feelings that the search environment evokes in both. Instructing must therefore

have an affective component explicitly dealing with the feelings engendered by the search environment.

6. *Incongruence or uncertainty.* Information professionals can gain a deeper understanding of searchers when they perceive them as being in a state of incongruence or uncertainty, needing to succeed while lacking sufficient knowledge.

User-oriented management of the affective information environment will take steps to legitimize the searcher's negative or stressful psychological state by presenting it as an ordinary problem created by the setting requirements rather than by the searcher's deficits.

7. *State of congruence with users.* Information professionals are in a state of congruency in relation to searchers when they accept searchers' weaknesses and ineptitudes and at the same time desire to help searchers acquire positive self-regard.

To be "accepting" simply means to acknowledge such insufficiencies as normal at the beginning, with routine remedies in the form of assistance, exploration, and instruction.

8. *Empathic understanding of users.* Information professionals can acquire an empathic understanding of searchers' internal frame of reference.

User-centered instruction or assistance takes the point of view of the searcher instead of the system. To do this adequately, research will have to discover empirically what users' cognitive and affective needs are while searching and build responses to these into systems.

The dynamic pace of change in the information world has spawned a new status for those who actively strive to work within information structures, that of the "perpetual novice."^[105]

9. *Lifelong novicehood.* The greening of the information world will have arrived when information professionals fully acknowledge the primary reality of the information environment i.e., novices will always be with us.

The recognition of this reality does not come easily, even for sophisticated observers. For example, Morris^[49] analyzes the role of expertise in the process of knowledge transfer, and refers to a study by Kaplan et. al.^[106] that tries to identify the differences between experts and novices in various disciplines. A major conclusion is that "experts are not experts by virtue of some generic problem-solving skill, but only in their knowledge of a particular content domain" and that "the way in which experts initially *perceived* a problem is what distinguishes them from novices; how they proceed after the problem has been set up was not significant" (p. 29).^[49] There is a general tendency on the part of information specialists to assume that the quicker we get rid of novices in the information world the better it will be, as if novicehood were a temporary state to be ended upon the completion of the

instruction. In addition, many believe that as computer literacy becomes more widespread, very little instruction in system use will be needed. There is as yet an insufficient consciousness among many professionals of the reality that *novicehood* in the information world never ceases.

In the mid-1970s, librarians were discussing whether or not patrons and researchers would want to do their own searching on the commercial information-retrieval systems and whether that would be a good idea. The end-user revolution is now behind us, and its character is beginning to unfold as an unprecedented number of people are attempting to operate on a daily basis within a rapidly evolving technological environment—so rapid that a new social phenomenon is occurring; we find that even as information professionals we are all novices all of the time, struggling (intellectually and emotionally) to learn, keep up with, and operate the latest versions of multiple systems, continuously adding new systems to our repertoire.

We need to understand this organic change in our information environments. What does it mean for a person to forever be a novice, to never know a system completely, to discover after months of use that an unknown easy shortcut could have saved much effort, to be deprived of support in acquiring system skills? Who does not feel this on a regular basis, whether it is students learning to search online catalogs and databases or librarians exploring Internet search engines? Are hackers and computing facility administrators exempt from “the state of novicedom?”

Information-literate novices

The information age has created a new status for users that may be referred to as “lifelong novicehood,” an expression that represents the reality for most people who are intermittent yet steady users of the information superhighway. The kaleidoscope of networked information systems requires novices or intermittent users to actively participate in the successful operation of these evolving systems. This interactivity requires *information literacy* because it involves a variety of information-management skills, including the following:

- Figuring out screen instructions and command option lines
- Understanding the notion of canceling a command
- Constructing a viable cognitive map of the system
- Maintaining routinized checking procedures for typing accuracy
- Paying close attention to command structure, spacing, and shortcuts
- Keeping notes that are retrievable when needed
- Retrying operations with slight modifications and refinements until they succeed

Before the advent of user-centered consciousness, the idea of “being information literate” and the idea of “being a

novice” appeared contradictory or mutually exclusive. However, although we see ourselves forced to assume life-long novicehood, there is no substitute for information literacy, and this has rightly assumed a topic of importance among bibliographic instruction specialists.^[80] As the user-centered revolution passes the point of no return, the information world is endeavoring to restructure in order to create a user-friendly environment for information-literate novices. Without information literacy, novices cannot function.

The Perpetual Novice

Currently, in libraries, campus computer labs, and computing center units we can observe confusion, inexplicable technical delays, and intractable passing of the buck regarding who is supposed to know what. This reflects the reality that technical and administrative experts in the information world normally operate in a mode that appears very much like the way novice users operate. This is because the hardware and software they get used to are frequently updated and made compatible with new hardware and software. Experts in the computer world can never stop having to learn a new system, thus being a novice user of it. The challenge of working out compatibility in each unit or location is intense, as is evident from newsgroups for systems directors and information professionals. The principle that novices will always be with us is thus an outcome that is a feature of the structure of the information world rather than of the mental state of users. The information world has the inherent character of changing at a rate faster than users can assimilate. They are thus in a perpetual state of information shock. User-centered consciousness can come of age by promoting an information environment that is designed for “the perpetual novice.”

Novices may take two paths one of which—if carried to its logical extreme—may lead to a “happy hacker” mentality; while the other path may lead to a state of being which I call “the perpetual novice.” In effect, I am saying that regardless of “how” you classify yourself when you first begin to learn the technology, some of you may overcome whatever reluctance you may have had initially to become enthusiastic users of these services, while others of you will begin to (or continue to) show some reluctance about this mode of communication in perpetuity. Ultimately, the latter group may turn into “perpetual novices” who “must” use the system for work and will do so, while still keeping empathy with the newbies. You may find yourself in that position because of your job requirements or social requirements or even an internal driving force that keeps you wanting to learn about new technologies though you know you will never grasp it all. Many things in this field (specifically speaking about telecom) and in our society are rapidly changing and one can find it difficult if not impossible to keep up with everything. I find the term “perpetual novice” or “perpetual newbie” very applicable

to myself. Partially due to my job, mostly due to my own curiosity. I am always finding myself in a game of catch up, even when teaching others my new “discoveries.”^[105]

A GRADUATE STUDENT WROTE

I think I approach anything computer-related from the perspective of “goodie, here’s a new challenge!” I always like playing or working on computers. Basically, the more “user-friendly” the computer is, the more I hate it!! I like the old low-level archaic systems. For example. I like MS-DOS. Unix shell, and OS/2’s shell. I hate Macs. . . I think part of this comes from a “hacker mentality,” whereby you think you are doing some wickedly complex scheming quite easily. Others get the impression that you are some kind of “wizard.” The whole thing comes back to bravado. I get really excited when I get far into a system, especially if I think I’m not supposed to be that far under the system.^[105]

In the last analysis, it seems, hackers and novices differ only in self-image. There is no big mystery about the expert and the computer hacker—they just never give up! Lifelong novicehood creates new kinds of challenges for information professionals because nothing can be taken for granted about what particular users may already know. An illuminating expression of this dilemma was posted to the bibliographic instruction listserv Bibliographic Instruction List (BI-L) by Rick Newell of Washington Library Network (WLN) in the fall of 1994.

This is going to sound like a very strange question: Do any of you ever give instruction on how to press keys on a computer keyboard? I do training for library staff (including clerks, paraprofessionals, and librarians) on Internet, online searching, etc. I just assume that everyone knows how to press keys, but I’m starting to conclude that this isn’t true. Sometimes people will hold a key down too long (especially the “enter” key), and of course the function of that key repeats, and they get unexpected results. Or when I tell someone to press “Control-C”, they don’t always know that means to hold “Control” and press “C”. Some people don’t know that F1 is function key 1, not “F” followed by “1”. I’ve always said I would like to quickly move beyond teaching “which key to press” and talk about more interesting things like search strategies, but I’m starting to think that perhaps more instruction is needed in the mechanics. I could point out all these “which keys to press,” and “how to press them” things at the beginning of each class, but I’m afraid that people who are already experienced computer users will be offended. Probably most BI-L subscribers teach college students who already are familiar with computers. Any comments??

There exists a wide range of experiences and skills across user populations; still, the majority of novice searchers are also novice computer users.

Surfing Versus Searching

We can gain a deeper understanding of what is user-centered by studying the growth of the Internet as a natural or cultural phenomenon. The spontaneous development of homepage architecture on the World Wide Web is an expression of the user-centered revolution. Through its worldwide telecommunications network, the information superhighway functions as a physical scaffolding for virtual cyberspace. Users are now *navigators*, and “cybernaunts,” a status equivalent to the *information literate novice*. It is now expected that an information-literate user can approach a terminal, launch an application such as Netscape, and begin exploring the multimedia global network of the World Wide Web. Visible command buttons on the screen and standardized pulldown menus allow the first-time information-literate user to surf around in cyberspace, traversing time and geography, hopping from hypertext links placed there by other cybernaunts eager to serve as travel guides and commentators. The term surfing expresses a certain freedom in navigating or gliding around at will, deciding to follow a link purely on the basis of a momentary attraction or curiosity, and backing out of it, retracing steps, or going on to new places. Although traditional search functions are available, browsing is the primary method of navigation on the Web.

Electronic Bookmarks

A truly user-centered feature of cyberspace is the universal availability of navigation *browsers* with hypertext capability that have two basic functions. One allows users to *navigate* by hopping from link to link at will, and the other allows users to retrace their steps in a variety of convenient ways. For instance, the bookmarks facility in many multimedia browsers on the Internet permits users to save any address of any location they travel to by creating a permanent personal address list that they can activate at any time and search, thus providing a permanent record of one’s travels through cyberspace. The bookmarks list is “hot” in the sense that one can select and click any item and be taken to that address location again almost instantaneously. This function is user-friendly and allows serendipitous browsing and collecting of links to be revisited and explored more fully at other times. In effect, the bookmarks facility for hypertext networks such as the World Wide Web permits users to create personalized indexes, catalogs, and personal information retrieval systems almost effortlessly and without advance technical skills.

Clearly, the next stage for end users is creating individualized information-retrieval and delivery systems on the Net. Many end users are already providing information services for themselves and interested others on the Web in the homepage format. Homepages permit end users to design information presentation, retrieval, and delivery systems tailored to the owner’s expertise and topical interests.

In cyberspace, everyone is an expert in self-defined specializations. “Websters” create personalized calling cards, resumes, family histories; they impart their knowledge on subjects, point visitors to other related or interesting sites, or provide a service of some kind that visitors may request. For example, Tony’s Bad Style homepage presents his evaluation of homepages that he visits. He makes it his business to travel the Web, critiquing homepages because he is interested in developing acceptable quality control standards for homepage structure and content and hopes to influence others with his prescriptive analyses. Some other examples include homepages dealing with selling products and services (e.g., magazines, advertise their print versions; record companies display pictures and bios of artists and you can hear part of a song; and shopping malls of various types are advertised), emotional support, searchable directories of visual artists with pictures of their works, gardening advice, home-buying advice, confessions, and a catalog of useless sites (like litter on the information highway). End users may also receive mail from visitors and have them fill out questionnaires directly on their homepage.

Navigation history

History is another user-friendly function of hypertext browsers that keeps track of every document one has accessed and highlights that link in a special color, irrespective of where the link occurs. World Wide Web indexes and documents each have unique access locations known as URL (uniform resource locator) addresses. When browsers click on a hot link that appears on a Web “page” (or screen), the client browser (e.g., Netscape) accesses that URL location through live telecommunications lines (telnet, FTP, etc.). The same URL address on a link can appear anywhere on anyone’s homepage or document. In addition, when one creates a link, one can choose any title or description for it as long as the URL address is the same, in other words, the same document or index page appears under many different titles or descriptive annotations throughout cyberspace. The history function shows users what pages or documents they have already seen at least once, even though the link names or titles are variable or entirely different. This is user-friendly because it allows greater control over navigation and helps users avoid endlessly reviewing the same material. With the history feature, the same document or file has a variety of different names, but this is an advantage, because it allows multiple independent access to the same information, not unlike cross-references in thesauri and subject indexes.

Personalized subject indexes

Another user-friendly feature of Web browsers allows novices to instantly construct individualized subject indexes on any desired topic or activity. Standardized subject indexes are easily accessed by clicking a link and are

maintained and updated as a free service from many sources on the Web—academic, commercial, and individual (e.g., Yahoo, Whole Earth Catalog, InfoSeek). These are user-friendly and contribute to more orderliness on the Internet. First-time users may also click on Netscape’s search button and type topics in natural language (e.g., automobiles, skin care, cats, museums, or Hawaii). Within seconds, a new document appears on the screen as a subject index containing hot links to addresses that relate to the specified topic. This list can be saved as a permanent file and one can collect as many as desired. Within minutes, a first-time user can create an individualized database on a topic for personal use or for the use of others.

Forces Against the User-Centered Revolution

It may be surprising to have to raise this issue, and yet familiarity with the information world today reveals the existence of social forces that act to divert or retard the user-centered revolution. Four such counterproductive influences follow.

Technophobia

It is ironic that many people experience an aversion to or fear of computers, because the user-centered revolution is taking place in an electronic information environment. Although unpleasant, this is nevertheless a normal affective response in human–machine interaction in the early stages of becoming information literate. The ability or skill to overcome technophobia is part of the repertoire of the lifelong novice. There may, however, be large individual differences in the time it takes to acquire self-confidence as a searcher or navigator, and there are conflictual and emotionally challenging intermediate states. User-friendly systems and affectively oriented instructions can ease the transition; yet being lifelong novices, people may regularly regress into technophobia when the old repertoire does not work with a new system. The kindly management of generalized technophobia remains a central goal of the user-centered paradigm as more and more novices of all ages and backgrounds begin to participate in the cyberspace world.

Information shock

A second counteracting force is *infoshock* or the emotional reactions of feeling overwhelmed by unfamiliar and complex information. Experience in an academic setting shows that students learning to use the Internet as a course-integrated assignment go through weeks of frustration, anxiety, and even depression. These are their reactions to being pressured by course deadlines while being challenged by what seem to be information deadends. Research is needed to discover effective techniques for managing users’ experience of information shock in the electronic environment.

Information illiteracy

If lifelong novicehood is to be endured by users, they need to be given *metatools* that empower them to operate by systematic trial and error instead of semirandomly or illogically. Information literacy skills provide users with the prerequisites of how to read instructions, evolve mental maps of systems, keep notes that are needed later, check one's typing, retrieve, filter, and evaluate information, and retrace one's electronic steps. Lacking these skills, information-illiterate users may be overcome by technophobia, discouragement, and avoidance. Information illiteracy creates an insurmountable barrier, defeating the gains of the user-centered revolution.

Maintenance cost

As the Internet grows, the cost of running it and keeping it user-friendly becomes a potential threat to the user-centered revolution. For instance, nonacademic users pay a monthly access fee and cumulative connect time. The latter cost can exert a prohibitive pressure that interferes with the convenience of browsing freely without undue concern for how long one can stay on a screen. In addition, millions of users have already moved past the navigation state to full-fledged membership as World Wide Web homepage owners. Millions more will follow. This means that one must rent disk space on a Web server. The space issue becomes potentially prohibitive even with academic and professional users who receive Internet services as part of their job setting. As more people begin to own virtual real estate in cyberland, space and traffic becomes forces that threaten users' ability to explore and build the virtual information world.

User-Centered Consciousness in Cyberspace

The rapid development of the Internet would not have been possible in the absence of the user-centered revolution of the past twenty-five years. Driving the mass explosion of the information world are entertainment technologies and information services. There is a sensitivity to "customer needs-based networking," as described by one commentator.

The newest mandate for the online information networks is to develop applications for the general public. This is the message conveyed by the feverish superhighway activity in Washington, DC, by the new commercialism cropping up everywhere on the existing networks, and, forcefully, by the joint venture takeover frenzy in the cable, broadcast, entertainment and general communications industries. The new dawning is focused on the great masses of potential general users, who so far never have experienced the joys of telnet, and perhaps never will have sufficient time, energy or interest to appreciate its more arcane beauties (p. 12).^[107]

Because "the new dawning is focused on the masses," it is thoroughly steeped in user-centered consciousness. But note a certain pessimism about users who "never will... appreciate its more arcane beauties." It may be better to work with an orientation that strives to eliminate arcane beauties and make them openly accessible to all novices. As more novice users join in, there is a growing need to demystify the Internet.

The cyberspace of the Internet has the potential to empower users by providing a public platform for individuals to display and share their expertise in a wide variety of areas (e.g., dog care, computer systems, racing cars, emotional support, poetry, and recipes). This explosion in self-publishing permits unprecedented self-expression and creativity, and mirrors the exponential growth of end-user computing. In these early days in the cyberspace community, a characteristic phenomenon is the willingness of so many people to post detailed answers to strangers' questions on electronic bulletin boards and discussion groups. One may wonder what motivates this kind of public spirited, "gift giving" effort. One webmaster who was asked this question said that he responds out of a sense of mutuality and identification with other webmasters who are stumped by some technical problem to which someone else may have found a solution. "The whole thing would stop working if we didn't come to each other's rescue," he insisted.

We are at the threshold of achieving universal access to the global Internet infrastructure. It is an exciting historical time when cyberspace communities on the World Wide Web are being founded in all departments of societal information activities—educational, scientific, governmental, cultural, commercial, artistic, and personal. Homepages of all types and functions spring up literally by the hour! There is a frontier spirit of pioneering and innovation that parallels population forces that brought immigrants to the new World and adventurers out West. The new attitude is thoroughly steeped in user-centered consciousness because *the cyberspace revolution is the user's revolution*. Hackers, net potatoes, scholars, students, marketers, consumers, publishers, public officials—these and others make up the Internet. They have all unwittingly taken on a new status, that of lifelong novicedom.

Community-Building Forces in Cyberspace

Just as there are social forces that counteract the user-centered revolution, those that operate in the progressive direction are no less vigorous and impressive. Two are mentioned here.

Cybersocialization forces

It is remarkable to observe the positive social forces that operate within the user-centered electronic revolution. *Cybercommunities* are virtual in the sense that they are

independent of place, geography, and even demographic variable. One may wonder what motivates thousands of people to build up the virtual architecture of cyberspace. Professional and commercial motives have not been among the principal initiating forces in the evolution of networking.^[108] Today, a search on “homepage” yields many more individuals, families, and membership clubs than businesses or institutions. We are currently on the threshold of an explosion in homepages and homepage development services. One educator has created a “generational homepage” involving new students every semester in a virtual learning community that produces an unending virtual superdocument on the topics of the courses.^[109] It is easy to imagine families producing and maintaining elaborate generational genealogical homepage multimedia scrapbooks on the Web, complete with home videos and family travelogues.

The homepage phenomenon can be seen as an expression in cyberspace of the spirit of frontier development. Librarians and information professionals will no doubt become involved in working with individuals, faculty, students, and community members to develop their own homepages for presenting and retrieving online information. This is a natural outgrowth of the traditional reader service, as homepages are personalized information delivery systems with resources collected by and for the individual. For example, faculty members may ask librarians to assist them in creating homepages for particular courses that include useful Internet addresses, the full text of course materials and lecture notes, and model student assignments.

Freedom

Surfing the net has become a technological expression of an individual's inalienable right to pursue happiness. Internet technology allows one to pursue only what one desires. Attraction is the decision point for traversing a path (or not). Just as people loved the advent of highways that allowed them to take off to wherever they pleased, today the information superhighway provides people with the new freedom of browsing where they will. Furthermore, social contacts in virtual reality take on new dimensions of freedom previously unattainable in human experience. *Cyberpersonalities* and “virtual selves” allow users to strip themselves of their regular identities and perhaps shed some inhibitions in the process. In cyberspace, everyone is an actor who can play different roles of choice and even become famous. This tendency to develop anonymous personas has been the focus of a warning cry in political places with the consequent promotion of regulation and legislative oversight of the Internet.

Roles of Information Professionals

Some in the field see that user-based methodologies can create new forms of data on library use that provide

opportunities “to redesign libraries in fundamental ways” (p. 301).^[110,111] The end-user revolution has engendered new roles for information professionals that place them directly within the sphere of user concerns. The trends toward creating information that exists only online, creating machine-readable text of older books, articles, and images, and providing online access to current text and information services, along with the online self-publishing explosion establish the new technological milieu for information professionals. With the advent of new research methods, the knowledge base on end users has grown and has focused on their inner world, establishing the new psycho-social milieu. The evolution in user methodologies represents a graphic shift in perspective on users from the retrospective, summative, distal data of surveys, to the concurrent, formative, proximal data of ethnographic methods. At this stage, theoretical integration of these approaches will promote a holistic approach in the further creation of the information environment.

User-Centered Revolution: 1995–2008

Diane Nahl

Information and Computer Sciences Department, University of Hawaii, Honolulu, Hawaii, U.S.A.

Abstract

This entry reviews a sample of current research on information behavior (IB), examines recent research on online IB and use of electronic resources offered in libraries, describes the state of user-centered design, provides evidence of a commitment to the user-centered paradigm in library and information science research and education, and presents the response to the unprecedented rise of online participatory culture.

INTRODUCTION

In the past two decades, the field of library and information science (LIS) has become increasingly multidisciplinary in theory building, research focus, methodological sophistication, and praxis. Library and information science programs have diversified their faculty, programs continuously update and create innovative curricula and degree offerings, and researchers collaborate with and borrow from communication, anthropology, cognitive science, and computer science among other disciplines. A “user-centered” individual, organization, business, locale, or system must focus on discovering and responding to actual wants and needs of the people determined to be the users. To that end, researchers and system designers have developed and adapted methods to obtain relevant details of user behavior in order to improve systems and services. A previous entry, “The user-centered revolution: 1970–1995,” traces the origins of the user-centered focus to a shift in clientele from experts to novice end users.^[1]

The user-centered revolution in library and information science was generated by the general availability of search technology for novice end-users who rapidly out-numbered experts and intermediaries. The needs of this new class of searchers have changed the priorities in the information environment. In response, researchers have developed new types of data that more closely represent users’ actual experience with systems. This interest led to an evolution in the methodologies applied to user studies over the past 25 years [1970–1995], from survey questionnaires and feedback forms, to interviews, journals, logs, and case histories. The development in methodology represents a shift in focus from gathering anonymous, statistical data on users, to individualizing users through ethnographic and psychological approaches.

The present entry reviews a sample of the LIS literature that treats user issues since 1995, with emphasis on topics

concerning the emergence, rapid expansion, and full integration of the World Wide Web into social life and work. This brief period has experienced unprecedented penetration of the user-centered paradigm. The literature reveals that by 2001 the user-oriented perspective had entered every LIS subarea.

The trend toward user-centeredness is termed “revolution” because software engineers and interface designers produced applications and systems experienced as hostile by many users. The computer revolution was brought about by technologists, however, as computer use expanded to the population at large, an increasing proportion of users found themselves in frustrating states of mind marked by puzzlement, anger, phobia, and helplessness. The computer engineering field was slow to address these user reactions and concerns. The general attitude toward “end users” was that improving their computer literacy skills would solve their problems. While the software and interface environment was experienced as psychologically hostile and unfriendly to millions of users, it was not recognized that systems were responsible for user-problems. By the time the Internet became popular in the mid-1990s “usability testing” had become a standard subject in interface design courses and texts. When software engineering adopted the human factors maxim of fitting technology to people instead of requiring people to adjust to technology, the burden of making systems work for people shifted to the designers and the user-centered revolution was underway. One indication of the deepening of the user-centered revolution is the dramatic upsurge in user-centered language in disciplinary databases and on the Web.

User-Centered Language

Earlier reviews of the print and online literature concerning the user-centered revolution covered material containing a variety of user-focused terminology.^[1] Table 1 shows that since 1970 the internalization of a

user-centered philosophy has given rise to continuously expanding user-oriented concepts that highlight the activities of interacting, experiencing, and participating online. Google searches were conducted on the terms used in the earlier print and online literature concepts and some related terms. Table 1 supports the conclusion that user-centeredness has become an essential concern to system architects in every content area.

Terms relating to user factors continue to proliferate, with 19 new terms added for the period 2001–2008 to the original set of eight terms in Table 1. In 7 years occurrence of the term “user friendly” increased from nearly 1.5 million to nearly 28 million postings, while “user centered” also grew from 33,000 to nearly a million by the end of 2008. Other terms with very large postings include usability (23 million), user experience (11 million), user defined (8 million), user generated (6.5 million), user created (5.6 million), customer experience (4.5 million), user contributed (4.5 million), and user input (2.8 million). On

<http://www.amazon.com>, 2051 titles appeared under the subject “Web usability” in December 2008, more than 30 times the 67 “usability” titles offered in 2001. The term “user-centered” retrieved 2569 titles in December 2008. The list in Table 1 is not exhaustive, and while search results are dynamic the increasing trend continues. A full analysis would yield many more related terms that emphasize a user orientation, and a requirement to pay attention to what people actually do while using systems and operating within information environments (IEs) in order to support, augment, and enhance their activities.

This entry reviews a sample of current research on information behavior (IB), examines recent research on online IB and use of electronic resources offered in libraries, describes the state of user-centered design (UCD), provides evidence of a commitment to the user-centered paradigm in LIS research and education and in libraries, and presents the response to the unprecedented rise of online participatory culture.

Table 1 User-centered terms: A comparison of early print literature and the Web

Print literature 1970–1995	Google.com September 2001	Terms searched within quotes	Google.com December 2008
user-centered	33,000	user centered	909,000
user-friendly	1,400,000	user friendly	27,700,000
user-based	34,000	user based	743,000
user-oriented	32,000	user oriented	435,000
user-responsive	800	user responsive	855,000
client-centered	22,000	client centered	828,000
human-centered	18,000	human centered	409,000
people-centered	13,000	people centered	189,000
	570,000	human centered	111,000
	251,000	user defined	8,000,000
	41,000	user needs	2,230,000
	595,000	user perspective	1,060,000
	39,000	usability	22,900,000
	18,000	usability testing	803,000
	6,000	user testing	962,000
	8,300	user evaluation	90,900
	16,000	usability evaluation	154,000
		usability engineering	223,000
		user centric	404,000
		user driven	626,000
		user created	5,660,000
		user generated	6,500,000
		user contributed	4,560,000
		user input	2,830,000
		user determined	83,800
		patron driven	6,290
		user experience	11,300,000
		customer experience	4,540,000
		user interactions	443,000
		interaction design	1,930,000
		user experience design	283,000
		user centered design	406,000
		user centered web design	6,250
		participatory design	172,000

DESIGNING HUMAN-CENTERED IES

Several large studies have produced findings to guide the continuing design of the IE. The IE includes all physical and online settings where people are engaged in the perusal and/or exchange of data, images, text, information, or knowledge, including details about anything in life such as work, events, beliefs, imaginings, relationships, health, entertainment, etc. An IE may be grounded in technological affordances such as computers and other telecommunications devices, or a self-contained setting such as home, library, school, home improvement center, physician's office, hair salon, neighborhood coffee house, or any community setting. The studies reported in this section reveal major trends in IB made visible through enormous and mushrooming public use of the World Wide Web over the past 15 years. The following top trends for libraries emerged in recent studies of user behavior, including users of public libraries, academic libraries, school libraries, government sites, etc.:

1. Increasing use of electronic resources in libraries
2. Search engine (SE) supremacy
3. Web 2.0 interactivity and participation
4. Difficulties with academic electronic resources

For most public and academic library users the convenience of full-text electronic resources makes them preferable to print material. People of all generations love SEs more than any other information retrieval mode, and libraries are responding with “next generation” online catalogs that resemble familiar SEs. The interactive applications introduced by Web 2.0 have sparked the public's imagination, and have increased the appetite for interactivity and establishing connections with others online. As a result, libraries have implemented a variety of Web 2.0 interactive services dubbed as Library 2.0 (see the section “Information is personal”). The escalating preference for a Web-style information seeking experience is evident in data from several studies where people report that the formality and structure of academic databases requires more effort, more time, and more technical vocabulary in queries.

Carol Tenopir's meta-analysis of over 200 research studies on users and uses of electronic resources provided in libraries yields a rich set of findings on user behavior and makes several user-centered recommendations. Tenopir found “Both faculty and students use and like electronic resources and most readily adopt them if the sources are perceived as convenient, relevant, and time saving to their natural workflow” and “Experts in different subject disciplines (work fields) have different usage patterns and preferences for print or electronic. There is no one right solution for services or system design for every subject discipline.”^[2] The wide variety of differences in undergraduate, graduate, faculty, and researcher uses of electronic databases challenge providers and libraries to

meet needs on many levels. Tenopir's review shows “The concept of a single typical ‘user’ of information systems is clearly a fallacy.” Some of the user-centered recommendations include

- Allow users to customize and personalize electronic resource pages.
- Publishers create products that better support the workflow of users.
- Recommend electronic resources to users to increase awareness of relevant material.
- Teach students how to evaluate found material and help them with search strategy.
- Develop virtual reference services to support increasing electronic resource use.
- Provide both “viewer-friendly” (html) and “printer-friendly” (pdf) full-text formats.

Tenopir's report provides a plethora of data illustrating the diversity of users and uses of electronic resources and the inherent complexity of the IE.

A 2007 Pew study, *Information Searches that Solve Problems*, found libraries performed well when people face personal problems that require obtaining information for decision-making:^[3]

Library help is effective. Among those who received help at the library, 88% say they found a lot or some of what they were seeking, including 38% who say a lot. By contrast, among those who did not seek help at the library, only 53% found a lot or some of what they were seeking, including 29% who say a lot.

Though in some studies Generation Y users (ages 18–29) report avoiding the library, Estabrook, Witt, and Rainie found that young adults in the Pew study are the heaviest users when it comes to looking for information about personal matters or anything else, and that they valued library resources and access to technology.^[4] One of the main user-centered findings from the Institute of Museum and Library Services (IMLS) *Museums and Libraries Engaging America's Youth* study encourages librarians to “substantively involve youth in program design and decision making” and recommends “Programs should strongly align institutional focus and audience needs, especially by performing needs assessments to inform program selection or design.”^[5] In November 2007, *Library Trends* issued a Call for Papers for a special issue devoted to exploring the current use of Web 2.0 technologies in libraries that serve teens, and how future services might be developed to better meet the needs of Web 2.0 savvy young adults. The issue focuses on the following user-centered areas:

- MySpace, Facebook, and other social networking sites
- Use of blogs
- Security and safety

- Getting staff and managers onboard
- Gaming—does it have a place in libraries?
- Online reading groups
- Podcasting—library tours and other uses
- Web 2.0 approaches to information skills
- Wikis and online communities

Involving tweens and teens in the design of Web 2.0 services is consistent with the deepening user-centered participatory trend.

The 2007 Association for College and Research Libraries (ACRL) Environmental Scan produced a set of Top 10 Assumptions about users of college and university information services.^[6] The research found that demand for online library services will continue to strengthen (p. 13):

Students and faculty will continue to demand increasing access to library resources and services, and to expect to find a rich digital library presence both in enterprise academic systems and as a feature of social computing.

The 2007 Scan also highlights the significant changes brought about by Web 2.0 and subsequent challenges of implementing Library 2.0 for improving infrastructure, contributing and creating content, and designing and delivering interactive services. Recent research in the application of user-centered social media in libraries is examined in the report; however, the area is nascent, rapidly evolving, and the professional literature continues to expand.

The Joint Information Systems Committee (JISC) study of college students and researchers in Britain, found they have become “information consumers” comfortable using commercial SEs, online library services and databases, wikis, social networking, and other forms of information access.^[7] Ian Rowlands describes “horizontal” information seeking behavior characterized by “bouncing, checking and viewing...” calling users “promiscuous, diverse and volatile.”^[7] Users in this study spent an average of 4–8 min on e-book sites, but did more navigating than reading, and exhibited “squirreling behaviour” in gathering information in case it might be needed in the future.^[8] As for online abilities,^[9]

Digital literacies and information literacies do not go hand in hand. A careful look at the literature over the past 25 years finds no improvement (or deterioration) in young people’s information skills.

However, a majority of students in the 2007 Educause study of Undergraduates and Information Technology reported that they use and are skilled with a wide variety of technologies, and only 26% indicated they wanted more technology training.^[10] Carol Tenopir uncovered evidence in the findings of a meta-analysis of 200 studies between 1995 and 2003 that these trends have been developing since the early Web began attracting users. For example,

“Most high school and undergraduate students turn first to the Internet for class assignments and feel they are expert searchers” and “Younger users rely on electronic resources more heavily and rate themselves more expert in using them than do older users.”^[2]

Eszter Hargittai studied the digital fluency of 1160 first year students at Princeton including their perceptions of their online skills as well as their understanding of online concepts.^[11] This wired generation reported high confidence in their digital abilities, “52.2 percent claimed to be fairly skilled, 33.0 percent believed themselves to be very skilled and the remaining 8.5 percent thought of themselves as experts” (p. 10). Hargittai had students rank their level of understanding to explore perceived knowledge of the online concepts, “frames, preference settings, pdf, spam, jpg, bookmark, newsgroup, mp3, and browser” and the more recent Web terms “bookmarklet, feed reader, malware, mashup, phishing, podcasting, real simple syndication (RSS), social bookmarking, tabbed browsing, torrent, tagging, Web feeds, widget, and wiki” (pp. 12–13).^[12] The *Oxford English Dictionary* defines mash-up as “a mixture or fusion of disparate elements” and *MSN Encarta* defines it as a “digitally created mix of songs: a song in digital format created by combining parts of different songs, for example the music track of one song and the vocal track of another.” While the majority of students gave high ratings on the basic concepts, on the more recent terms most reported low levels of understanding. Hargittai proposes 11 user-centered areas of skill that need greater attention in research and teaching (pp. 13–14):

1. Effective and safe ways of communicating with others.
2. Knowledge of how to contribute to group discussions and share content.
3. Knowledge about and use of tools.
4. Knowledge of what is available.
5. Ability to find content.
6. Efficiency in Web navigation.
7. Ability to assess source and message credibility.
8. Understanding of privacy issues.
9. Understanding of security issues.
10. Knowledge of where and how to seek assistance with questions.
11. Customization.

Taken together, these studies identify the IB of the Net Generation of college students as driver of the expansion in the use of interactive technology in society, particularly on campus. These digital natives were born into technology and will continue to drive its social uses; however, they need to deepen their understanding of and abilities with new forms of content provision.

In the space of one school day, 21st-century children might converse with their friends using instant messaging,

watch webcams of live events happening anywhere in the world, read e-books that contain links to relevant information, use videoconferencing to share ideas with students at schools in other states or on other continents, and use the Internet to access databases and websites containing information on a topic of choice.^[13]

Net Gen search behavior emphasizes speed, simplicity in concept, interface and database, full gratification in answers, and ease.^[14]

Still, the international 2005 OCLC Perceptions of Libraries and Information Resources study found that most people are not aware of online library services.^[15]

The findings indicate that information consumers view libraries as places to borrow print books, but they are unaware of the rich electronic content they can access through libraries.

The vast majority (84%) found information using a SE and were very satisfied with results (93%), claiming that the quality and quantity of information provided is higher than from libraries. These user assessments are based primarily on the generally high confidence users express in their abilities to evaluate the quality and trustworthiness of retrieved information (86%). Other studies of the predominance of SE use among college students found that Google was used 45% and library catalogs used 10%.^[16]

- Students prefer to locate information or resources via a SE above all other options, and Google is the SE of choice.
- Students' use of academic resources is low.
- Students find it difficult to locate information and resources.
- Students may trade quality of results for effort and time spent searching.
- Students' use of SEs now influences their perception and expectations of other electronic resources.

Frequently cited reasons given for low use of academic electronic resources are the need to find, choose, and search different databases; hierarchical arrangement, complexity, and differing interfaces; the lack of total full-text retrieval; and the technicality of academic vocabulary combined with less full-text makes it difficult to retrieve relevant material.

The perceived difficulty of online catalogs and subscription databases, the need to justify their escalating cost, and the development of the SE, the greatest technology trend of the Internet age, has stimulated universities to create novel user-centered approaches to win back students to their resources. Indiana University has an agreement with SE ChaCha, touting its "Human Guide" component that allows online catalog users to link to a librarian for assistance during a search session.^[17] ChaCha

maintains a knowledgebase of vetted answers, so as it is used could become more valuable to the university community. The interface is similar to the sparse Google search page with a Guide button on the results page, and ubiquitous Google Ads, revealing that online catalogs, like other SEs, can be accepted as revenue-producing entities. Trend watchers point out that user-centeredness is key to successful catalog improvement.^[18]

The most significant difference between traditional library catalogs and the "next generation" library catalog lies in: 1) the enhancement of the discovery process and 2) providing services against the collection beyond simple identify. Putting the users' needs and characteristics at the center of the query process will greatly enhance the discovery process.

The broader interface design community has come to a similar conclusion.

Centrality of Users in Design

It is recognized that interfaces have physical, social, cognitive, and affective aspects.^[19–24] A central concern of human-computer interaction (HCI) research has been to determine the effects of human physical, cognitive, and affective characteristics on the interactions between users and computers for specific tasks. As HCI researchers from a variety of disciplines developed models of human activity and used these models to design new interfaces, it became evident that a new design protocol must include a variety of interactive process and social approaches.

The UCD movement in computer science, particularly the area of HCI, has transformed a field which has shifted orientation, has redefined its scope, and has adopted a process approach that emphasizes the user experience, not only in interaction with information technology, but interaction with information in any form, in any setting, and in collaboration with others. In the second edition of *Interaction Design*, Helen Sharp, Yvonne Rogers and Jenny Preece describe the new user-centered process approach as "... creating user experiences that enhance and augment the way people work, communicate, and interact."^[25] The four main principles of interaction design may be applied in any discipline or setting and are not limited to computer interface design or telecommunications technology design.^[26]

1. Identifying needs and establishing requirements of the user experience.
2. Developing alternative designs that meet those requirements.
3. Building interactive versions of the designs so that they can be communicated and assessed.
4. Evaluating what is being built throughout the process and the user experience it offers.

Inherent in each of these activities is the focus on the agency of individuals and groups in their use of information systems. Interaction design seeks to discover user priorities and desires in order to facilitate and accommodate those goals in interactive environments. To that end “user experience architects” (UX) utilize a variety of process and ethnographic methodologies to gather user data throughout the stages of design. “Experience designers” seek feedback on thoughts, feelings, impressions, and preferences through observing users engaged in natural settings, interviews, questionnaires, performance tests in the lab, having users interact with prototypes, having users think aloud during activities, biometric measurement during activities, having users participate in and contribute to design sessions, and other process methods.

These user experience design principles are expressed in greater detail through design principles that have evolved within the HCI field:^[27,28]

- Visibility
- Feedback
- Constraints
- Consistency
- Affordance

In practice these five principles interact, creating complex dynamics that must be worked out with users within the design process. Affordance is a key concept that helps users notice what they can do at any given point in use or on a given screen, for example, a visible link invites (affords) clicking.^[29]

The marked shift in orientation from an exclusive focus on “system” to “user and system” to the “user experience in interaction with systems of any type” profoundly influences the design process. Sharp et al. distinguish between “usability goals” and “user experience goals” and emphasize that each design must address both types of user goals with different approaches and analyses. Traditional usability goals inherited from the field of human factors include the following quality components:^[30]

- Effectiveness
- Efficiency
- Safety
- Utility
- Learnability
- Memorability

Some usability goals include specific attention to identifying errors and how satisfied users are with the design.

User experience goals constitute a different, highly affective set of positive and negative qualities, feelings, and preferences. For example, designers elicit user responses regarding whether an experience is:^[31]

- Satisfying
- Engaging
- Entertaining
- Helpful
- Motivating
- Pleasurable
- Provocative
- Challenging
- Frustrating
- Boring
- Annoying

User experience goals are often said to be subjective while usability goals are considered objective. However, researchers find great value in open-ended responses offering rich, spontaneous user discourse that reveals the centrality of affect in information reception and use. Capurro and Hjørland make the point that “Meaning is, however, determined in social and cultural contexts.”^[32] Individual interpretive responses, therefore, reflect the community practices that enable designers to create supportive and symbiotic systems.^[33]

Participatory design, also termed cooperative design or contextual design, is a user-centered approach that integrates users throughout the process as design partners.^[34–36] This design philosophy is deeper than UCD, which includes user input at various points throughout design, while participatory design makes users codesigners. For example, the International Children’s Digital Library (ICDL) project of the Human-Computer Interaction Laboratory at the University of Maryland hired several children of varying ages to work with researchers in the Lab designing the site for children.^[37] Researchers involve children from many different countries and regions of the world who contribute in a meaningful way to the site’s design as well as to the growing content it offers. Children contribute to design elements, help select books to add to the international online collection, and write reviews of their favorite books for other children.^[38] International Children’s Digital Library researchers study the children’s response to reading e-books as well as to reading other children’s online reviews, finding that children incorporate novel expressions describing how a book made them feel. Their affective language is added to metadata to help kids in searching the collection because it reflects their own way of thinking. For example, ICDL added several affective search terms contributed by kids, including happy, sad, scared, and funny, among others.

Divergently, user-centered pioneer Jakob Nielsen cautions that designers should not rely on what users say about an interface because their descriptions may be neither accurate nor reliable. To design an easy-to-use interface, he recommends paying attention to what users do and not what they say, because users tend to base their evaluation of a product on surface features, which are often quite different from reports based on actual use.^[39]

Another example is the drop-down menu. Users always love the idea: finally a standard user interface widget that they understand and that stays the same on every page. However, while they offer users a sense of power over the design, drop-down menus often have low usability and either confuse users or lead them to unintended parts of the site.

Yet despite such problems, the drop down menu is present in most interactive systems. Nielsen warns that focus groups can give mixed results.^[39] When discussing past behavior, users self-reported data is typically three steps removed from reality. This is because users cannot remember specific details of complex processes and tend to fill-in memory gaps with what seems plausible. Second, people construct things or speculate about what might be easier or harder for them rather than rely on actual recalled aspects. Concurrent data gathering methods such as observing users interacting with a system or recording think aloud protocols can provide more accurate data on what users actually experience in a process.

Designing for Diversity

Global computing has necessarily strengthened the fundamental user-centered concern for how to accommodate the diversity of users, which shows itself in individual differences in perceptual and motor capacity, in cognitive ability and intellectual skills, in emotional coping skills, in handling complexity, as well as in personality, cultural background, and expectations. Computer literacy depends on memory for detail and order and the ability to solve problems to make appropriate decisions. Since these cognitive abilities are normally distributed in a diverse population, half of the users of a system will have below average intellectual skills, yet many interfaces must accommodate the wide range of skill in the entire population.

The design community has responded to people with diverse physical challenges by creating adaptive hardware and software. These efforts are aided by the mandates of equality of accessibility in the Americans with Disabilities Act.^[40–43] People also differ in perceptual skills such as time perception and scanning ability to locate information on screen displays. There are both individual and culturally based orienting habits and mindsets that the computing environment must accommodate.^[44] Affective habits also vary in a diverse population, for example, moods or motivational states of users vary from hour to hour, day to day. Some respond to lower levels of frustration while others tolerate a bit of anxiety and uncertainty. Illness or injury, drugs or medication, sleep deprivation, and emotional distress affect perceptual and cognitive abilities. Eventually, such diverse conditions must be anticipated and provided for by system designers.^[45,46]

Cognitive problems of users involve difficulties in acquiring progressive computer literacy skills for many whose educational background has not prepared them adequately with basic skills. They are overwhelmed by the bewildering complexity of software and hardware options in an era when designers still believe that simplicity is a sacrifice rather than a desired feature. Libraries have created many new services to bridge the digital divide, for example by engaging tech-savvy teens to teach senior citizens computer, networking, and gaming skills that help people overcome limitations, understand technology, and increase their participation in the life of the community and their families.^[47,48]

Standardizing UCD Principles

Inspection of design Web sites demonstrates a strengthened advocacy for users and a high degree of agreement concerning what constitutes good UCD. One example is the updated and expanded IBM design specifications:

In the following four sections, this site addresses the challenge of creating great user experiences through the discipline of User Engineering, supported by design guidelines, tools and other relevant materials.^[49,50]

The shift in terminology to the more encompassing “user engineering” that incorporates UCD, illustrates the deepening of the trend toward holistic design, and the opening of the design process to include frequent and systematic feedback from potential and future users. The previous 2001 IBM document pointed out that the Web connects everybody to everything with a single interface but cautioned that there is a difference between physical access and functional use since numerous people who may be connected are nevertheless incapable of using many of the available systems.

Many people acknowledge and accept the standards for such things as power voltage, power plugs, and even e-mail headers, but deny the need for standardizing user interfaces. They argue that users are intelligent and instinctive individuals and can adapt to any given design. It is true that users can adapt to almost anything. They surely had to do so in the past. Why should users have to adapt to machines? Do they voluntarily or involuntarily adapt to machines? Research on human factors in human-computer interaction shows that users of a new interface demonstrate a consistent desire to get started right away. . . This distinct desire or preference forces them to figure out. . . the interface without the benefits of a user-friendly design.^[49,50]

Despite the humanizing shift in design philosophy, it is common to struggle with technology and design during routine information tasks. For example, a study of 50 state health department sites reported that universally they are

deemed not user friendly.^[51] People are supposed to be able to conduct a variety of medical information tasks using these sites such as filing medical claims, comparing health care providers, determining eligibility for assistance programs, and becoming aware of and informed about services. Two-thirds of the sites had a reading level too difficult for an average person, many did not provide for non-English speakers, and more than half “did not meet the minimum recommended accessibility standards...”^[51]

In addition, as desktop and laptop systems have become more powerful, operating systems and applications have become more complex. Both affective load and cognitive load rise with uncertainty, and the frequent transitions to upgrades or new software makes it increasingly difficult for an ordinary user to install a system and its components. Replacing its focus in 2001 on standardization and universality of interfaces to solve ease of use problems, IBM’s 2008 design site content emphasizes value, diversity, personalization, and collaboration.^[49] Eleven design principles are provided and the fourth is Users:

Principle: Users

Description: Each group of users must be identified and characterized. This includes identifying the user goals and how they are measured. This is critical data for the Business Model work product and for tracking progress during the design process. The total user experience must be defined for each user group. Those aspects addressed by the project are identified, consistent with the business goals. Details of the tasks performed by each user group must be recorded, together with all important measures. In addition, information must be collected on how users wish to perform their tasks.

Purpose: Provide a clear understanding of the users’ world and what it will take to satisfy their expectations.

User eXperience Research gathers and records all user requirements including who they are (roles), what they want to achieve (goals), how they wish to do it (tasks), and their success criteria (measures & targets).

Ideally, typical or target users are incorporated into the design process to test the design until it is accepted. IBM invites visitors to its Web site to volunteer for user experience design studies.^[52] As the Web grows, usability becomes more important because users are often lost or get stuck, not knowing what to do next.

Jakob Nielsen discusses Web usability principles and what to avoid.^[53,54] Nielsen’s annual Top 10 Mistakes in Web Design essays document numerous ongoing follies of design and the consequences in lost productivity, and lost revenue due to user frustration and loss of customers, including not answering users’ questions, inconsistency, user-hostile messages, obtuse page titles, animations,

pop-ups, advertisements, and more.^[53,54] Still, the ubiquitous and obtuse “404 Not Found” Web error message continues to plague users:

We understand what 404 means: Page Not Found. But the average internet user has no idea what 404 means or what to do about it. To them, it’s yet another unintelligible error message from the computer. Most 404 pages are unvarnished geek-speak.^[55]

The Department of Health and Human Services has produced a set of extensive usability guidelines based on research intended to “...reflect HHS’ commitment to identifying innovative, research-based approaches that result in highly responsive and easy-to-use Web sites for the public.”^[56] The current set of *Guidelines* increased by 10% to 209 items, demonstrating the growing complexity of creating usable and acceptable sites. Chapter two of the *Guidelines* is devoted to Users, Chapter 17 covers Search, and Chapter 18 is devoted to Usability. Search includes the following user-oriented *Guidelines* to support term discovery:^[57]

Guideline: Construct a Web site’s search engine to respond to users’ terminology. Keep in mind that designers’ preferred keywords may not match users’ preferred keywords, and content writers may overestimate the specialized vocabulary of their audience. (p. 5)

Guideline: Provide templates to facilitate the use of search engines. Templates are predefined sets of keywords that help users select relevant vocabulary for their search topic. (p. 9)

The *Guidelines* recommend arranging topics in hierarchies. Similarly, the usability chapter reports that^[58]:

Inspection methods, such as heuristic evaluations or expert reviews, tend to generate large numbers of potential usability’ problems’ that never turn out to be actual usability problems. (p. 1)

Guideline: Solicit usability testing participants’ comments either during or after the performance of tasks. (p. 3)

Therefore, system-centered usability testing that employs inspection evaluation is inefficient in comparison to user-centered testing that isolates germane problems sooner. The *Guidelines* recommend the use of think aloud or retrospective critical incident methods to ensure discovery of the most salient user requirements. The goal of universal usability and ease of use will continue to be a challenge to the design community into the distant future because the diversity of users and uses ensures that one size cannot fit all.

One of the underlying forces working against user-friendly software, hardware, databases, digital libraries, and content-laden Web sites was termed “infomania” in

2005 by Edwin Hallowell, also referred to as information overload or Attention Deficit Trait (ADT):

Infomania is the mental state of continuous stress and distraction caused by the combination of queued messaging overload and incessant interruptions.^[59]

Zeldes, Sward, and Louchheim report that knowledge workers typically accomplish a mere three minutes of uninterrupted work during a task. Sources of distraction include “e-mail, instant messages, phone calls, text messages, and coworkers” among others.^[59] Incessant incoming information accumulates and pressures people to attend to it, process it, file it, make decisions with it, organize it, store it, and delete it. This situation creates stress as people experience frequent frustration in information-intensive environments, and the resulting losses in productivity can soar to billions annually.

SPREAD OF THE USER-CENTERED PARADIGM IN LIS

Researchers in virtually all subareas of LIS have adopted a user-centered perspective in their investigations. While many cite Dervin and Nilan’s 1986 *ARIST* review article as the inception of the user-centered turn in LIS, some prominent researchers have published historical reviews tracing its origins to the 1950s and 1960s studies of information practices of scientists in particular disciplines as well as other groups.^[60–63] Marcia Bates credits the work of Stanford communications professor William Paisley who focused on behavioral aspects of information use.^[61,64,65]

Current areas of special interest include: user generated content, IB models, emotional aspects of information seeking and use, information architecture, building community networks, Web 2.0 social software, open digital content, virtual services, and gaming, among others.^[66] Mike Eisenberg encourages libraries to lead in the rapidly evolving technological environment, where social media dominate in a “parallel information universe,” where content is delivered and users are interactively engaged through a variety of online devices, applications, and services.^[67] Inspection of recent conference programs in information science and technology shows a prevailing user-centered concentration in research.

Professional Conferences with a User Focus

American Library Association’s (ALA) Office for Information Technology Policy (OITP) and the Association for Library and Information Science Education (ALISE) jointly sponsored a 2008 session on “Participatory

Librarianship and Web 2.0 in the Curriculum.” The call for participation reflects a sense of urgency to integrate new user-oriented services into LIS curricula to ensure that graduates are prepared to enter a more user-defined IE:

The library landscape is constantly in flux. New technologies, new practices, and new theories are the sign of an active field. However, these dynamic forces also lead to confusion and conflict. It also leads to a spate of new services and functions that are sometimes awkward to integrate into existing research, operations and curricula. In today’s world of Web 2.0, Library 2.0, social networks, blogs and wiki’s what concepts are durable and what is new that must be imparted to the next generation of professionals?^[68]

The variety of Web 2.0 applications continues to swell so that a critical process for adoption must be developed to equip graduates with adequate tools for making new service decisions. For example, the 2007 ACRL New York Annual Symposium, “Library 2.0 a New Social Model” illustrates the demand for instruction in the application of social media. It offered practitioners three sessions that covered “Social Software in Academic Libraries,” “Technical Services 2.0: “Mashing up” Traditional and New Services,” and “Library 2.0 and Web 2.0, Changing the Face of Professional Development.”^[69]

The Computers in Libraries 2008 program lists sessions on SecondLife, YouTube, and other Web 2.0 topics:^[66]

- Social software
- Communities and collaboration
- User generated content
- Engaging the audience
- Gaming and learning
- Open source

The user-centered focus was evident at the American Society for Information Science and Technology (ASIST) 2007 themed, “Joining Research and Practice: Social Computing and Information Science,” including presentations on

- Social information architecture
- Participation behavior
- Social tagging
- Folksonomies
- Social computing
- Online communities
- Blogs and wikis for scholarly communication
- End-user collection building
- Digital natives

The ASIST 2008 annual conference program “People Transforming Information—Information Transforming People” continues the strong focus on social interaction:^[70]

- Individual identities and how they are transformed by the impact of information technologies.
- The societal archive—is it disappearing and/or being marginalized?
- Societal attentions and how emphasis on information technology either allows or hinders these.
- Openness, access, and privacy issues.
- Generational, economic, and sociocultural dimensions of impact of information on people's lives.
- Cognitive and emotional aspects of interactions with information.
- Reshaping the boundary between personal and public information space.
- The effect of collective information creation on authority and trust.
- Information by the people for the people.
- The role of information in connecting people and community building.
- How well is current technology meeting human needs, and what should future technology research and development involve to better meet our needs?

The American Society for Information Science and Technology (ASIST) held its first Social Computing Summit in 2008, to focus on “Social networking services, data portability, open social networks, mobile services, social computing and politics, global voices, social computing and the enterprise, and youth social computing.”^[71]

The Annual Research Symposium of the Special Interest Group on Information Needs, Seeking and Use (SIG USE) takes an inherently situated, social, constructivist, relational, interactive, and holistic approach to the study of IB.^[72,73] Special Interest Group on Information Needs, Seeking and Use is the leading ASIST SIG for user studies and has published two edited volumes of IB research and theory.^[24,74] The 2006 Symposium focused on emotional design and affect in IB, and the 2007 Symposium featured research on the use of mobile devices during a wide variety of user-driven information-intensive activities:

- Searching WebMD
- Checking stock portfolios
- Meeting up through *dodgeball.com*
- Chatting with friends on MySpace
- Playing online games
- Sharing photos
- Making plane reservations
- Paying bills and shopping

The Information Seeking in Context (ISIC) conference that originated in 1996 is entirely devoted to the study of situated IB, examining an ever-widening variety of particular user groups in specific information contexts and settings.^[75,76] A sample of the ISIC 2006 conference program presentations illustrates the current trend in

diversification of the user-centered paradigm in user group, methodology, and granularity of analysis:

- Uncertainty
- Interpersonal information seeking
- Information sharing
- Personal information seeking
- Motivation and information seeking

Investigations of everyday information seeking is a burgeoning area that has attracted experienced information retrieval researchers who have turned their attention to the micro level to study the information needs and uses of particular user groups within social contexts. These efforts to further specify levels in the human aspects of IB will continue to extend to narrower domains and into deeper layers of thinking, perceiving, learning, valuing, and accepting information. The Second International Symposium on Information Interaction in Context (IIX) exemplifies this user-centered thrust.^[77]

- Case studies, field experiments, simulations, etc. of context-sensitive information seeking and retrieval.
- Context-aware retrieval models.
- Relevance feedback—implicit and explicit—and query modification issues for capturing context.
- Other approaches to eliciting, identifying, and expressing/capturing contextual information.^[78]
- Task-based interactive information retrieval and seeking behavior.
- The effect of genre, media, language, modality, and structure on context.
- Personalized and collaborative information access in context.
- Contextual information interaction theory.
- Interactive information retrieval and interface issues.
- Nature of relevance in contexts.
- Measures of performance in context and situation-sensitive information access.
- Test collections for context-sensitive research.

There was some focus on user perspective at the IA Summit 2007, themed “Enriching Information Architecture,” but one year later at IA Summit 2008 the theme “Experiencing Information” focused entirely on the user experience.^[79,80]

- Information quantity and the experience of choice
- The timing of information encounters and information use
- The subconscious consumption of information
- Rapid or intuitive processing of information
- The social and participatory aspects of information and information communities
- The wide range of information media: the Web, virtual worlds, ubiquitous computing, mobile technology, physical spaces

The Association for Computing Machinery (ACM) Computer/Human Interaction 2007 Conference, CHI 2007, highlighted the continuing efforts of the HCI community to humanize the interface and to design for interaction and the user experience:

- Beyond usability: Social, situational, and contextual factors
- Rethinking humans, computers, interaction and design
- People looking at people
- Emotion and empathy
- Programming by and with end-users
- Ethnography
- Capturing Life Experiences

These conferences and a growing group of others demonstrate that information science and computer science research has taken the user-centered turn. It follows that degree programs preparing information professionals and information scientists have altered and enhanced curriculum to support users in the IE.

The Rise of Informatics and Participatory Culture

A study of 26 LIS programs was conducted between 1998 and 2000 in the Kellogg-ALISE Information Professions and Education Reform project known as KALIPER. The results of this detailed case study analysis revealed six trends affecting curricular change.^[81,82] The second trend that emerged from an analysis of program mission statements, course descriptions, course titles and syllabi revealed a predominant focus on the social and cognitive aspects of information, information systems, and information use.^[84] The programs emphasize user constructs and dynamics that permeate their core and elective curricula in the areas of information seeking, user behavior, user needs, user-centered information services, and user engagement practices.^[85] Markey warns programs to look beyond the user-centered paradigm to prepare future information professionals because, due to the spread of information and communication technology (ICT), disintermediation will likely displace libraries in that domain. She recommends, “Instead, programs should stake out unclaimed or disputed areas such as the organization of information, content creation, authoritative information, and/or collection preservation.” Informatics has emerged within several disciplines as a user-oriented specialty.^[86–92]

Informatics refers to the study of information systems, particularly the relationships among people, information, and information technology. Undergraduate and graduate programs in informatics offer a definitively human-centered approach to the study of information systems and technology. Students completing these degrees develop conceptual understandings of information and technology, a variety of technical skills, a human-centered perspective in designing, implementing and evaluating information

system use, engagement with communities of practice to foster networking, they share tools and resources, and work with open source “communityware” information and content management systems that are designed for public use. Ann Bishop and colleagues in the University of Illinois Community Informatics Initiative^[93,94] focus on understanding the social context that has led to the digital divide, and work to develop models for public libraries to collaborate with underserved groups in the creation of innovative technology-based information services relevant to people’s everyday lives.^[95]

The core of the CII is community inquiry: collaborative action to create knowledge and technology connected to people’s values, history, and lived experiences; the development of models of engagement that are just, democratic, participatory, and open-ended; and the integration of theory and practice in an experimental and critical manner.

As further evidence of the social participation trend in curricula, the theme for the 2008 meeting of the ALISE was Community Engagement: Integrating Learning, Research, and Practice. American Library Association’s OITP published the Participatory Librarianship Starter Kit^[96] that encourages creating participatory networks, and enhancing material offered to users by linking topics to a variety of resources (conversations) from the library, the Web, the community, and beyond, including existing sets of “answers”:

Simply put participatory librarianship recasts library and library practice using the fundamental concept that knowledge is created through conversation. Libraries are in the knowledge business, therefore libraries are in the conversation business. Participatory librarians approach their work as facilitators of conversation. Be it in practice, policies, programs and/or tools, participatory librarians seek to enrich, capture, store and disseminate the conversations of their communities.

For example, virtual reference service aims to “look at the core of the reference process as a conversation between a librarian and a patron.”^[97,98] Reference conversations proceed through exchanging understandings and “are ultimately a learning act.” The focus on human interaction, participation, and the value of acting together to change lives for the better, orients information professionals to maximizing the social utility of technology and content or expression by gaining technical skills, networking skills, engagement skills, and needs assessment skills.

Some refer to this human-centered activism as evidence of a Copernican paradigm shift from a primary focus on libraries and librarianship to a focus on information, from organizing information containers to understanding the role of information in people’s lives and helping them make productive uses.^[99,100] This change in

locus was first seen in the flurry of programs adding information to their names, missions, goals, and objectives, and course titles, and in user studies applying qualitative and ethnographic social science methods to investigate the human experience in needing, accessing, and using information. The impetus for understanding users' IB can be traced to the increasing pressure of an intensifying societal expectation that people become informed in every aspect of life including health, legal, insurance, personal finance, consumer product, and environmental knowledge, as well as interpersonal competencies or emotional intelligence.^[101] A responsible person can no longer simply rely on professionals to advise and recommend, instead, one must become informed through personal research and obtain second opinions to make intelligent choices about available opportunities, options, or treatments, and one must use information to help avoid disease, disability, penalties, fines, or unfavorable judgments, and to make informed decisions.

By "life information" is meant information needed for successful living. The area of need ranges all the way from sheer survival (stay away from dogs that walk funny and foam from the mouth) to the most advanced forms of self-realization (where can I study ceramics or transcendental meditation?). The scope of information falling under this rubric is greater than may at first appear. It includes vast amounts of information about how to do many different things in one's culture that will be acceptable and lead to one's survival and emotional satisfaction.^[102]

The information age provides abundant information to those who are connected to the networks, nevertheless, one must make the necessary effort to value, notice, identify, locate, obtain, store, evaluate, and utilize information; determine its ultimate effectiveness; and often, report the results to others (family, physicians, friends, fellow students and teachers, employers or coworkers, etc.) and find it again at a later time on a different occasion. In addition, there is the ever-expanding information universe of work that continuously pushes people to update and upgrade their knowledge and skills within an IE that demands lifelong learning. Informatics research will continue to gather importance because of the trend toward a continuously enlarging responsibility to obtain and manage personal information.

Multidisciplinary Influences in LIS Curriculum

The field of HCI has been at the forefront of the UCD, interaction design, and user experience design movement.^[103] Library and information science programs and I-Schools have developed curricula based in the computer science design philosophy, which has become increasingly multidisciplinary through integrating psychological, sociological, and anthropological theory and methods. As

evidence of the expansion of the trend to incorporate users in interface design, usability assessment texts have emerged that treat the needs of information-intensive, content rich Web sites produced and maintained by librarians for their user communities.^[104–108] Stephen Bell advocates applying design thinking "to help users accomplish their work by removing barriers or inefficiencies. . ." and introduces the user-centered IDEO design method and the Designing Better Libraries blog.^[109–111]

Courses offered in information programs have diversified from the single usability or UCD course to include varied offerings and tracks. Some examples include

- Usability Analysis
- Information Users in the Knowledge Society
- Information Behavior
- Seminar in Information Use and Users in Context
- Information Architecture
- Communities of Practice
- Assessing Information Needs
- Human Dimension in Information Systems
- Interface and Interaction Design

In 2008, the University of Michigan School of Information (SI) launched six new specializations, including four user-centered tracks^[112–115]:

- Social Computing
- Incentive-Centered Design
- Community Informatics
- Information Analysis and Retrieval

The courses in these areas integrate such user factors as design ethics, psychological principles, interaction principles, social network analysis, online communities, computer-supported cooperative work, public goods, personalization, information use in communities, and user contributed content, among others.

The San Jose State University School of Library and Information Science (SLIS) was first to create a Second Life portal to deliver courses in the virtual world that allow students to create services, build information service environments, and conduct research in the SLIS virtual information space.^[116] Courses for practitioners in the Virtual Worlds CE Series were offered for the first time in 2007 at the University of Illinois Graduate School of Library and Information Science:

- Second Life 101
- Introduction to Virtual World Librarianship
- Survey of Librarianship in Virtual Worlds
- Technical Skills for the Virtual World Librarian
- Intermediate Virtual World Librarianship—Programming and Planning
- Libraries and Immersive Learning in 3D Virtual Environments

- Working with a Class in Second Life
- Setting Up an Educational Presence in Second Life

The I-School at the University of Washington began offering a Certificate in Virtual Worlds for professionals seeking advancement in the following new skill areas:^[117]

- Design virtual worlds, including multimedia
- Build in and account for human interaction
- Program and integrate with databases
- Evaluate the effectiveness of virtual worlds

The strong multidisciplinary user-centered trend in LIS curriculum development will continue and widen beyond system design and use into traditional areas of the field including archives, preservation, serials, acquisitions, information organization, reference services, and information access.

Information Literacy Mandates

Information literacy (IL) is an area of curriculum development that has lagged behind the profession. Heidi Julien analyzed the curricula of 93 LIS programs worldwide and determined that most programs did not have a course that prepares graduates to take on responsibilities for managing existing IL, digital literacy, and information fluency programs, including designing, planning, and teaching sessions, workshops, and full courses that are predominant in libraries around the globe.^[118] In academic libraries, IL librarians must provide leadership in campus efforts to integrate IL components in General Education reform, and in school libraries developing IL skills is fundamental to every grade level. Julien argues for curriculum development to address this neglected core competency.

Information literacy, media literacy, digital literacy, and technological literacy coalesce in the online environment. In the past two decades, IL programs, user instruction services, instructional Web sites, and interactive online tutorials have proliferated in libraries worldwide. Information fluency has become a strong movement, evidenced in the mission and goal statements of academic, public, and school libraries which commonly cite endeavors to teach users to become independent, critical, and ethical information seekers and information users. The annual survey of freshmen in 700 American colleges by the University of California at Los Angeles (UCLA) provides a representative picture of the IL skills of entering students.^[119] The survey reports that 76% used the Internet for assignments but only 35% said they critically evaluated information found in Internet searches.^[120] In the past decade, accrediting bodies began mandating IL instruction in higher education. Outcomes assessment of IL competencies has gained momentum driven by the mandates from accrediting bodies, that is, schools must

demonstrate that graduates are information literate.^[121] Standard 2 states: “Baccalaureate programs engage students in an integrated course of study . . . to prepare them for work, citizenship, and a fulfilling life. These programs also ensure the development of core learning abilities and competencies including . . . Information literacy . . .” Other accrediting bodies have similar requirements. The outcomes assessment model fits within data-driven strategic planning models that predominate in libraries. Professional associations have developed IL standards, competencies, and curricula to assist information professionals in measuring gains in skills.^[122–126] The Reference and User Services (RUSA) division of ALA published six Guidelines for the Introduction of Electronic Information Resources to Users, of which the fourth is devoted to user-centered instruction. Guideline 4.3 addresses individual user factors:^[127]

4. User Education/Instruction

4.1 Determine the appropriate type and level of instruction for a new electronic information resource.

4.2 Determine the extent to which the service should be incorporated into existing user instruction and the extent to which new instructional sessions or methods would be helpful.

4.3 Design user instruction to accommodate various learning styles and experience levels and include a combination of point of use instruction for individuals, group instruction, peer assistance (both user-user and instructor-instructor), tutorials, documentation, and/or signage.

The American Association of School Librarians (AASL) Standards for the twenty-first Century Learner overlap significantly with the ACRL Competencies while acknowledging that “Learning has a social context.” In addition to acquiring critical thinking and evaluation skills,

The Standards describe how learners use skills, resources, and tools to

3. share knowledge and participate ethically and productively as members of our democratic society;

4. pursue personal and aesthetic growth.^[128]

The AASL Standards’ emphasis on the social aspects of learning, the ethical use of resources, and the value of self-improvement reflects the user-centered active learning movement in education that integrates learning community, collaborative learning, reflective learning, service learning, problem-based learning, inquiry learning, and informal learning models. These relational approaches continue to rise in prominence in higher education, particularly with the influx of social media and gaming models in learning, and will likely influence the future revision of the ACRL Competencies.

Originating in 1990, the Instruction Section of the International Federation of Library Associations (IFLA) has worked to promote IL skills in libraries worldwide. The 2006 Guidelines set international standards for global citizens.^[129,130]

Information skills are vital to the success of lifelong learning, employment, and daily interpersonal communication of any citizen, such as when a person needs information about health services for someone in his/her care, or a student requires specific information to complete an assessment.

The IFLA Guidelines take a constructivist approach to lifelong learning of IL skills, and overlap with the ACRL and AASL standards, with a strong emphasis on ethical use of information systems and resources. The IFLA Guidelines do not mention other social aspects present in the AASL standards, such as the social nature of learning and aesthetic values of learners. IL standards for these professional groups will evolve to address social learning and personal values as the user focus continues to strengthen.

INFORMATION IS PERSONAL

As a result of the societal forces of participation and community engagement, theory building has been developing at the intersection of the fields of communication, anthropology, sociology, and the psychology of information retrieval. The “sense making” approach was formulated by Brenda Dervin whose model is thoroughly user-centered, and grounded in constructivist assumptions about information seekers and users.^[131,132] In this view, information is defined in terms of people’s attention, processing, seeking, and use. Dervin’s approach to user-centeredness complements Carol Kuhlthau’s constructivist approach to information problem solving and information counseling, Marcia Bates’ cognitive-behavioral approach to understanding searching, and Paul Solomon’s approach to situated information discovery.^[133–135] These person-centric approaches view the IE of systems and interfaces in terms of users’ behavior. Information behavior is defined as what users do when they handle information and adjust to it.^[136] “Information behavior...encompasses information seeking as well as the totality of other *unintentional* or *passive* behaviors (such as glimpsing or encountering information), as well as purposive behaviors that do not involve seeking, such as actively *avoiding* information.” Salient user factors include: what they do and see, what they think or know, and what people feel that motivates them to continue or quit, to be satisfied or to continue searching, to strive to comprehend or

remain bewildered, to continue as a novice or strive to become an advanced daily user. In the purest sense in this approach there is no information, only situated IB, that is, information is embodied in IB.

The study of IB in a rapidly evolving technological society demands close attention to a full range of broad and specific user dynamics.^[24,74,137] The multidisciplinary theoretical approaches in IB research acknowledge the centrality of the user’s values, feelings, and perceptions in the information reception and use process. Each approach focuses on how the perspective of users determines their IB. Findings from IB research show that users are highly interactive, with dynamic motives and intentions. As goal-directed sense-makers, users are seeking meaning, bridging information gaps, dealing with uncertainty and anomalous states of knowledge, translating their own ideas into system terms, actively updating personal frames of reference, filtering both information and feelings, and applying personal constructs in the information seeking, reception, use, sharing, and creation process.^[24] The users have become the creators, producers, and disseminators of content, therefore information retrieval systems and environments must concretely incorporate this reality into design to achieve the user-friendly systems that people need.^[45,138]

In 2003 nearly half of all Internet users had added online content through file sharing, building or posting to Web sites and blogs, or posting content for businesses and organizations.^[139] According to Henry Jenkins, director of MIT’s Comparative Media Studies Program,

...a participatory culture is a culture with relatively low barriers to artistic expression and civic engagement, strong support for creating and sharing one’s creations, and some type of informal mentorship whereby what is known by the most experienced is passed along to novices.^[140]

The forms of participatory culture include memberships in online communities (*Friendster*, *Facebook*, *MySpace*, *Twitter* and other more specialized online communities such as *LinkedIn*), metagaming, producing digital sampling, “skinning” and “modding,” videomaking, fiction writing, zines, “mash-ups,” working in teams to complete tasks and develop new knowledge (e.g., *Wikipedia*), and shaping the flow of media (podcasting, blogging).^[141–145]

Wikipedia defines metagaming as “a broad term usually used to define any strategy, action or method used in a game which transcends a prescribed ruleset, uses external factors to affect the game, or goes beyond the supposed limits or environment set by the game.” MSN Encarta defines “digital sampling” as an “electronic process used in telecommunications for transforming a constantly varying (analog) signal into one composed of discrete units, a digital signal” and one definition for “skinning” is “to

change the appearance of images produced by existing software, without changing their function.” A description of modding via Technology Source is, “Many of today’s games—especially the first-person perspective, three-dimensional world games—are “open” to mods (modifications) of an enormous number of their features, including the environment, the characters, and the game play. Through modding, it is even possible to construct an entirely new game.”

A user-centered emphasis enhances access to the full range of information activities, and advocates integrating the individual via engagement and involvement into the ongoing social practices of the community, so that technology works synergistically in the user’s daily life of activities.^[146] Library 2.0 pioneers advocate a major shift in perspective from “library functions and resources” to customer and user goals, interests, and desires for simplicity and ease of use. The digital user’s focus is on participation, collaboration, membership, social networking, teamwork, task optimization, and successful completion. Self-expression is thus performed within intersubjective environments of communities of practice, and libraries are uniquely well placed to establish and foster active user communities by utilizing the new social media.^[147]

Web 2.0, Library 2.0, User 2.0: The Social Software Revolution

After the total acceptance of SEs, User Generated Content (UGC) is the biggest user-centered trend affecting libraries, publishing, and news media. User Generated Content involves the use of social networking, folksonomies, blogs, wikis, and other interactive online facilities that allow self-expression. User Generated Content, also called user defined content or user contributed content, has surged as people flock to online sites to ask questions and seek answers, deposit their thoughts, musings, views, strong opinions, knowledge, evaluations and reviews, images, activity status updates, creativity, and vision for others to read or ignore, perhaps to attract comment and interact in an exchange of ideas or strong disagreements and agreements. The social software movement has sparked controversy over the traditional top-down prescriptive model of information standards and authority and the disintermediating, bottom-up inductive dynamic of social media. Professional news organizations now provide e-mail and blogs welcoming user input, and regular segments are devoted to “news” reported by “citizen journalists” who log in to leave information, including e-mail, voicemail, photos, and video. For example, the major cable networks have instituted the user-centered i-Report, U-Report, and News to Me segments, and viewers are implored to take polls on questions of the day and post comments and questions on the network’s Facebook, MY Space, and Twitter pages. Some consider this

democratizing trend to be positive, persistent, and highly collaborative, while others deplore its baseness, lack of authority, anonymity, irresponsible demagoguery, and other cultural offenses.^[148,149] As the lively debate evolves, the newly empowered authors and content creators will continue to find their voice and to prevail in Web 2.0 territory and beyond. Library users have begun to interact and provide input using the Library 2.0 participatory services designed and implemented by tech-savvy Librarian 2.0 information professionals.^[150–161] Authors will write regularly updated reports about their initiatives for at least two years on a wiki hosted by the Association for College & Research Libraries (ACRL).

Library 2.0 represents the library that immerses itself in the advanced functionality of Web 2.0 technology to benefit the user experience by providing access to content through a personalized and co-constructed infosphere. According to Habib,

The term Library 2.0 was introduced by Michael Casey in September 2005. . . . The term was exposed to a wider audience when Michael Stephens discussed Library 2.0 on the ALA’s Techsource Blog.^[162]

The “Librarian 2.0” according to Stephen Abram,

understands his or her users at a deep level – not just as pointers and clickers. Librarian 2.0 understands end users deeply in terms of their goals and aspirations, workflows, social and content needs, and more. Librarian 2.0 is where the user is, when the user is there. This is an immersion environment that librarians are eminently qualified to contribute to.^[163]

Social software for library-related interaction and services incorporates blogs and RSS feeds to involve users in participatory exchanges that link comments, chat rooms, online discussions, blogs, wikis, photo and video sharing sites, podcasts with streaming media, e-mail, and Instant Messaging (IM).^[164] Through these recent technological developments librarians have become involved in creating conversations, connections, and community within their user populations.^[158] According to Abram “we are entering a period of enormous change - far greater than what we’ve ever experienced in our lives to date.”^[163] The new global transformation in the infosphere is powered by interactivity on an unprecedented scale. Social collaboration is as old as community and society, however the social-technological environment has become organic and symbiotic.^[23] Despite the digital divide, human-machine symbiosis encompasses daily life for greater numbers of people, such that there is hardly a portion of the day that people are not connected to some technological device, creating and exploring intersubjective communication spaces in which our daily life of thinking, feeling, and sensing is shared virtually and co-experienced with many others.

The early Web environment also offered new ways for people to connect, including e-mail, Usenet groups, hyperlinks, directories, surfing, SEs, online shopping, and e-Bay bidding.^[165] Beyond connectivity and access to vast information, Web 2.0 provides the living thrill of participatory culture where people take a personal hand in co-constructing a dynamic information world of *intersubjectivity*.^[166–168] Social theorists and researchers use the term intersubjectivity to refer to use of the shared knowledge of jointly accepted group practices when people interact. Individual values, meanings, information, and knowledge are shared and dynamically created in social interaction, hence “Knowledge and knowledge structures are neither objective nor subjective, but intersubjective, produced within a shared system of meanings.”^[168] Social networking magnifies the intersubjective sphere, rendering the former Web paradigm limited, formal, and impersonal. Today’s Web “page” is dynamic as the screen explodes in striking visuals and sounds, streaming video, sidebars with animated ads and polls, RSS content updated to the moment, and with deep level inserts like content filters, cookies, notebooks, dictionaries, SEs, polls, maps, fill forms, interactive graphics, widgets, customization and personalization, user tags and metadata, archived discussions, user reviews, ratings, and comments. Social technology has become an organic component of community life, a transformative user-generated trend in computing and communication.

Technology users today are empowered and enhanced because people can do more, see more, hear more, network more, enjoy more, and create more of what they want together. The meaning of technology has shifted from “computation” and “connection,” to collaboration, co-construction, community, continuity, and co-presence in real time and in virtual senses.^[169] Web 2.0 is explosively producing global intersubjectivity within an infosphere that is organized in channels defined by what people do, think, and feel on the daily round.^[170] Floridi defines the infosphere as “the whole informational environment constituted by all informational entities (thus including informational agents as well), their properties, interactions, processes and mutual relations. It is an environment comparable to, but different from cyberspace (which is only one of its sub-regions, as it were), since it also includes off-line and analogue spaces of information. We shall see that it is also an environment (and hence a concept) that is rapidly evolving.” Web portals and user gathering places are organized by special interests, niche topics, and targeted activities. Originally information space was organized by topic or subject matter, but the new social information dynamic has added a layer of content that is organized by activity. People go to sites to do things: to shop, transfer funds and pay bills, meet with online friends, send e-cards, trade stocks, find map directions or an address, order pizza, play online games with avatars, contribute to collaborative wikis, consult live

online reference librarians, attend classes in immersive learning environments, see and contribute to the latest postings on blogs of interest, view and respond to updates on friend’s activities, upload and download songs, videos, photographs, ringtones, resumes, and tax forms, etc. In social media users define the uses.

Stephen Abram provides a list of the technologies that “serve as the emerging foundation for Web. 2.0”:^[163]

- Really simple syndication (RSS)
- Wikis
- New and revised programming approaches like AJAX and APIs
- Blogs and blogging
- Commentary and comments functionality
- Personalization and “My Profile” features
- Personal media such as Podcasting and MP3 files
- Streaming media audio and video formats
- Reviews and user driven ratings
- Personalized Alerts
- Web Services (e.g., virtual reference service)
- Instant messaging and virtual reference including co-browsing
- Folksonomies, tagging, and tag clouds
- Photo and video sites (e.g., Flickr, Picasa, YouTube)
- Social networking software
- Open Access, Open Source, Open Content
- Socially driven content
- Social bookmarking (such as Delic.io.us)

Michael Stephens also identifies the following:^[159]

- Building a community Web site with a blog
- Libraries and social sites like MySpace, Facebook, YouTube
- Messaging in a 2.0 World: Twitter & SMS
- Podcasting

A survey of public libraries in South Carolina confirms that social technologies are quickly transforming public libraries into participatory gathering places.^[171] Services offered include instant messaging for reference services (30%), photo sharing accounts (23%), library blog (40%), and wiki (10%). More than half of the librarians have an instant messaging account, and one in three have a personal blog and participate in adding content to a library wiki. Libraries are also experimenting with building online communities, online library book clubs, user forums, offering library news using RSS, hosting webcasts and webinars, providing widgets for building personal digital collections^[172–175] and digital DVD downloads, among many other user-centered interactive services. Some librarians caution that simply adding interactive services does not guarantee that people will use them or provide input, and that needs assessment, active participation of librarians and continuous evaluation are necessary to success.^[176]

Benefits of Tagging and Social Bookmarking

The 2008 Library of Congress report on the Future of Bibliographic Control opened the gates to UGC in stating “User-contributed data, such as reviews or rankings, can help other users identify resources of possible interest to them.”^[177] In an unprecedented agreement with the image-tagging site Flickr.com, the Library posted large collections of digital photographs with a request for input, “You’re invited to help describe photographs in the Library of Congress’ collection on Flickr, by adding tags or leaving comments.”^[178] The Library intends to harness “key caption information” from masses of people viewing the images on the Flickr Commons site, effectively making indexers of users.

For libraries, “Tagging, as with del.icio.us and other social bookmarking tools, lets libraries label books in ways that make more sense to patrons than traditional subject headings.”^[179] Sites such as LibraryThing and Shelfari provide libraries with a user-centered approach to reducing barriers to participation, enabling users to post reviews, ratings, and tags to ease retrieval for other users.^[172] The marvel is that people are keen to descriptively tag items, to comment on their usefulness, and to receive recommendations based on similarly tagged items. Users also want to build online collections using widgets that post book jacket images for new books with certain tags, or random books, or favorite books read by friends, or books one has read in one’s lifetime, or books one plans to read, or the ICDL Children’s Book of the Day, etc. The same holds good for music and video. Users love to arrange and organize information. The next generation online catalogs incorporate tagging and other social software features, but also promise “opportunities to get away from the OPAC and focus resources on new areas, such as 3-D information visualization, mass digitization, Library 2.0, and metadata related to digital resources.”^[180,181]

Second Life Immersive Social Learning Environment

It is often claimed that Generations X and Y have been brought up in a world of videogames that have become more complex and graphically elaborate since their inception in the 1970s with the simple yet fascinating Pong computer game. Web 2.0 librarians, young adult librarians, and instruction librarians see an opportunity in designing user-centered services involving games, gaming, and gamers. Libraries that offer ludic programming have instituted videogame tournaments and have created IL instruction using gaming formats.^[182–185] Sharon Stoerger notes that participatory information technology is habit forming to the “Net Generation or Millennials” who have been raised on games and the Internet.^[186] The teaching approach of lecture, textbook, and report assignment that has served previous generations now seems

insipid, dry, and staid. Today’s young adults are enlivened by participation and engagement, from which comes involvement and excitement. There is less value attached to merely new information if it is not optimized by participatory experience in an interactive media-rich virtual environment. This social reality laid the foundation for adapting a virtual world gaming environment to provide library services. In the Second Life virtual environment thousands of patrons visit Second Life Libraries every day, experiencing in world reference services from the main teleport landing on Info Island I.^[187] Volunteer avatar librarians serve the many virtual reference stations through the Alliance Library System.

According to technology forecasters, “By the end of 2011, 80 percent of active Internet users (and Fortune 500 enterprises) will have a second life.”^[188] In 2007 more than eight million people had “resident accounts” in the collaborative virtual world of Second Life, one of dozens of virtual environments specialized for children, tweens, teens, or adults.^[189] In April 2006, the Alliance Library System began work in the 3-D multiuser virtual environment (MUVE) of Second Life, helping to develop in-world libraries, collections, and immersive reference services.^[190] What began as a single library, in less than two years grew to 43 islands of the Info Archipelago where over 1000 avatar librarians provide in-world reference service, create and provide virtual spaces for students and educators for classes and collaborative projects, create teleport boards linking the libraries and collections, market and hold events to support literacy, reading, authors, artists, and technology development for libraries, and develop collaborative projects with colleagues, students, and others.^[191] Avatar librarians also provide course and research support to educators teaching in-world, and offer orientation classes and professional development programs for librarians and LIS graduate students who wish to explore work in Second Life.^[192] The myriad advantages of 3-D virtuality for avatar librarians include flying, teleporting, automatic language translation in reference and other collaborations, serving a global clientele and new forms of diversity in user avatars, collaborating with colleagues worldwide, enhanced social and professional networking via affinity groups and friending, enhanced social presence for distance communication, virtual building, scripting, filming, and creating innovative interactive information affordances. The constructivist virtual environment stimulates imagination and feeds innovation in developing new library and information services. Second Life offers a complete research environment for avatar information studies, information seeking in virtual worlds, virtual IL, embodied distance learning, HCI interface studies, AI, and other areas.^[193] In 2008 the American Library Association opened a virtual Washington Office in Second Life’s Cybrary City on InfoIsland.^[194]

The wildly popular social networking sites have sparked another user-revolution that is inherent in the new “participatory culture” consciousness.^[195,196]

The Second Life browser software comes equipped with build-tools, group options, communication tools such as chat and instant messenger, and a menu-driven video capture tool for users to record “machinima” of their experiences, simulations or live events. Machinima is familiar to millions of gamers around the world and is defined as “animated filmmaking within a real-time virtual 3D environment.”^[189]

Librarians also create “story-based *machinima* instruction series” that combine filmmaking, animation, and 3-D video-gaming for instructional delivery. In the machinima (machine-cinema) environment, avatar actors and events in the virtual world are controlled by scripts chosen by users. Some avatar librarians create machinima to document and archive informational, cultural, and educational events in Second Life.^[197] On video-sharing sites, collaborative software allows users to edit or piece together a multimedia film from the raw footage of video uploaded by other users, enabling group editing and storyboarding for joint media productions and community information sharing with collaborative content creation.

Library and information science programs have begun to offer courses and workshops on social computing and the immersive learning environment Second Life that focus on how to make use of the game-based, virtual environment created by the engaging online Second Life world for instruction and self-development. The University of Illinois GSLIS wants to “take the library forward to its future incarnations” beyond the “traditional read-lecture-and-discuss format,” making use of the new game-based immersive learning technology that can provide new ways of library instruction and reference services.^[198] In 2009, the University of Washington I-School began a three-course Certificate Program in Virtual Worlds designed to prepare professionals for work in virtual environments.^[117] A *YouTube* video shows how the San Jose State University School of Library and Information Science is integrating Second Life into its graduate teaching and research program.^[199] The eLearning virtual campus contains classrooms, individual computer workstations, buildings, faculty offices, walkways on grassy paths, and an eCafe used as a social gathering place. The virtual version of the San Jose LIS School sits on a virtual island surrounded by other islands that house libraries and projects by other institutions. Lili Luo and Jeremy Kemp’s research on early adopters among LIS educators found that Second Life is considered a viable instructional platform for 85% ($n = 20$) of respondents.^[200] In the broader context, the 2008 JISC *Serious Virtual Worlds* report provides a review of the use of virtual worlds to support learning and training, including a review of the field and

case study examples, a typology and a list of virtual worlds, and a prediction that future education will take place within virtual worlds.^[201]

Although virtual worlds have been around for over 20 years, it is only really in the last five years that the real potential for virtual worlds has been recognised, and the next 20 years could bring about a virtual world revolution that has the capability to radical (sic) shift how we learn. To ensure that this revolution is successful at engaging students and supporting the development of higher order thinking skills it is vital that we work together as a community and integrate our plans so that the learners of the future have an educational system that gives them an enriched learning experience, does not suppress creativity and helps to create a cohesive community that works together for the greater good.

To ensure that this happens, we need to monitor closely what the exact implications will be of virtual self-organised communities, we need to refocus our educational practices upon the key aims and objectives of our society and we need to find ways to promote excellence in cross-disciplinary research and methodologies.

Learners are fast becoming co-creators of their learning experiences, and virtual worlds and Web 2.0 offer the most constructivist platforms for those activities. The Web 2.0 and 3D infosphere is not merely a more complex information platform for providing users with interactive Web applications. Abram sees the evolving interactive technology as a vehicle for providing “deeper user experiences.” The Internet is thus not merely more collaborative, but transformational. Collaborative constructions are not merely social, but a new way of creating content, meaning, and value.^[202] Open communication, decentralization of authority, and disintermediation of specialty are producing a new intersubjectivity whose content is a living expression of humanity, diversity, and inventiveness.

Information Ethics

As vast numbers of people have entered the online domain they have created new uses and abuses of its systems and content. An ethics vocabulary is emerging with terms users need to understand such as cyberethics, computer ethics, information technology ethics, global information ethics, Internet ethics, content filtering, digital rights, acceptable use policies, electronic privacy, and netiquette.^[203–208] The ethical implications of online use are central to increased legislation and social debate over proper and improper or illegal use of online systems. There is much for users to be concerned about in the online environment, including: e-mail scams, phishing, pharming, and spam, spy software, information security, identity theft, cyber-stalking, grieving, unobtrusive monitoring, information warfare, firewalls, reliability, privacy

policies, and Web spoofing, as well as defense against virus, destructive worms, Trojan horse, denial of service, and other malicious code attacks. All creators of information products and artistic content must be concerned about the ease of online copyright violations, censorship, identity, and intellectual property theft.

A user-centered discipline has emerged in response to a phenomenon that challenges privacy and security of personal information. “Exoinformation” refers to the electronic trail left behind when people are active online: accessing a Web site, sending e-mail, participating in chat rooms, shopping online, filling in registration forms or applications, entering a search query, checking a stock quote, clicking a link, time spent on a page, and many other forms of information left behind through use. With the onset of ubiquitous, integrated, global computing, the sheer amount of exoinformation about ourselves that we leave behind is enormous: what route we take to work at what speed, what we bought at the supermarket, who left a message on our voicemail, what documents we accessed in an electronic library, which news we read daily, when our parents passed on and from what cause, who our online friends are, our favorite books, music and DVDs, what groups we belong to, and so on. According to Benjamin Brunk “an entire industry devoted to collecting and making sense of exoinformation already thrives.”^[209] This naturally raises concerns among users and watchdog groups over misuse, abuse, and criminal activities involved in stealing, manipulating, and profiting from such information. System design and information policy has been evolving a user-centered focus to protect people online; however, such efforts add significantly to the information management work for each individual, as passwords and privacy policies accumulate in an overwhelming barrage of new data to track and keep. In addition, fears are sparked routinely with pop-up warnings and alerts threatening dire consequences if a user ignores the interruption.

CONCLUSION

Complexity is continuously increasing in the IE and human complexity remains a vast domain to explore. It is early in the development of widely used online systems, and there is too little research on interface use and design in LIS and in HCI, particularly with new Web 2.0 applications and virtual platforms. Originally LIS studies concentrated on subject experts and expert searchers, and few in HCI have studied large information systems and their users. Even the rising tide of LIS and HCI Web studies is too small to predict a universal simplified system, and findings about user diversity from the past decade suggest that is a false goal. The rise of virtual environments as immersive learning and work platforms portends greater change and innovation for the information professions. It is clear that user-oriented research will continue to evolve in many fields of study where

understanding IB is considered important to facilitating progress. The LIS field is the most advanced discipline in user-centered focus, theory, methodology, and application. Multidisciplinarity has enhanced the field’s ability to diversify and extend the user-centered paradigm. This continued evolution has the potential to inform other disciplines concerned with understanding IB. Just as twentieth century general systems theory revolutionized thinking and research across disciplines, twenty-first century user-centered research will revolutionize theory and praxis applicable to diverse settings, industries, disciplines, communities, and groups. The user-centered trend led by LIS has become as pervasive as ubiquitous computing and is fast becoming user-driven.

This total involvement or “immersion” in the ecology of information technology has become the new basis for learning. Technological affordances are synergistically linked to sensory organs and motor output, mediated by cognitive and affective procedures that validate belongingness and self-confidence.^[23] Sensory-motor engagement with technological affordances is critical to the process, but it is not the primary motive for the experience or participation. The value and motive for interacting with technology centers on users’ feelings in conjunction with their thoughts, which are necessarily grounded in social group practices. From this arises an intention to interact with a technological affordance. People are motivated to optimize information by engaging with it through their collaborative goals and plans. Recent research and praxis show that people have a strong desire to create and publish content, to write and publish reviews of content, to index and tag content, and to organize and arrange content, and this for individual as well as altruistic uses. The increasing democratization of the IE has engendered new roles for information professionals. In the current and evolving IE, people are free to engage systems to communicate, design, and create. Blending games, community, and learning produces engagement, interactivity and fun, and that core of the user experience will continue to drive the development of user-centered systems and services in the twenty-first century IE. It is clear that user-centeredness will be implicit in all systems.

Peter Ingwersen

Royal School of Library and Information Science, University of Copenhagen, Copenhagen, Denmark

Abstract

The domain of user-oriented and cognitive information retrieval (IR) is first discussed, followed by a discussion on the dimensions and types of models one may build for the domain. The focus of the present entry is on the models of user-oriented and cognitive IR, not on their empirical applications. Several models with different emphases on user-oriented and cognitive IR are presented—ranging from overall approaches and relevance models to procedural models, cognitive models, and task-based models. The present entry does not discuss empirical findings based on the models.

INTRODUCTION

The Cranfield model of information retrieval (IR) has dominated IR research until recently—up to 2005. Currently, user-oriented research is popular but theoretical development is quite scarce. The focus of system-driven research is IR algorithms and their evaluation. Algorithms are evaluated for their capability of finding topically relevant documents.

Laboratory IR has recently been challenged by progress in the research into *relevance*, *interactive IR*, and *information seeking*. Recent work in analyzing the concept of relevance has resulted in identifying higher-order relevances, such as cognitive relevance and situational relevance, in addition to algorithmic and topical relevance. Real human users of IR systems introduce nonbinary, subjective, and dynamic relevance judgments into interactive IR processes. Moreover, recent theoretical and empirical work in information seeking suggests that IR is but one means of information seeking, which takes place in a context determined by, for example, a person's task, its phase, and situation. For larger tasks, one may identify multiple stages, strategies, tactics or modes of information access, and dynamic relevance. IR strategies, tactics, and relevance assessments are therefore affected by the stages of task performance.

Because of these empirical findings and theoretical arguments, the traditional Cranfield model of IR evaluation was challenged for its (lack of) realism. It has therefore been suggested that the developers of IR algorithms should consider how the algorithms are to be evaluated—in which frameworks and how to guarantee validity. Ingwersen and Järvelin^[1] discuss the

limitations of, and challenges to, the system-driven laboratory IR.

User-oriented research on the IR phenomena was (and is) not necessarily based on any specific epistemological perspective. It might be practice related or very pragmatic in scope. On the other hand, since its start in 1977, the cognitive approach to IR could briefly be characterized as user and intermediary oriented, with an explicit epistemic approach underlying its scope. Since mid-1990s the approach has gained momentum and turned into a holistic view of *all* the interactive communication processes that occur during information transfer—including those associated with the retrieval engine. Simultaneously, a user-centered IR research shifted focus from exploring traditional (scholarly) online interaction with the human intermediary as a central actor to web-based IR with the end user as the player.

A cognitive turn took place in IR in the early 1990s. Robertson and Hancock-Beaulieu^[2] see this turn to consist of three facets (or revolutions) that are crucial to understand in order to proceed toward a more integrated (holistic) theory of IR: the cognitive, the relevance, and the interactive revolutions. The cognitive and interactive revolutions combined entail the ideas that personal information needs ought to be treated as potentially dynamic, not static. They may change over time—probably due to learning and *cognition* in context during IR interaction. Relevance assessments, hence, also become dynamic and may take place in a variety of dimensions, so that the traditional topicality as a measure of relevance does not stand alone.

The present entry first discusses the domain of, and the kinds of models one may build for, user-oriented and cognitive IR. The focus of the entry is on the models, not on their empirical applications, and therefore we present

several models with different emphases on user-oriented and cognitive IR—ranging from overall approaches and relevance models to procedural models, task-based models, and cognitive models. Due to space limitations, we had to choose between candidate models to present, and therefore some excellent models had to be excluded.

THE DOMAIN OF USER-ORIENTED AND COGNITIVE IR

When the system-driven IR research could be seen to neglect information seekers in its modeling and experimentation, user-oriented IR research focused precisely on them. The complementary nature of these two areas may be seen in the light of Fig. 1.

The system-driven IR research focused on the left side of the figure, on authors' texts, their representation, queries, and retrieval. Text includes all kinds of signs included in documents, such as video, photos, and sound. The user-oriented and initial cognitive IR research focused on the right side, on users' problem space, information problems, requests, interaction with intermediaries, interface design, and query formulation but hardly on analyzing authors' texts, their representation, queries, or IR techniques. With the turn into a holistic view in the 1990s of *all* the interactive communication processes that occur during information transfer, the cognitive approach finally encompassed all the components of Fig. 1—including the algorithmic and document areas. The cognitive and user-oriented approaches were compared to the systems-driven one in several respects (Ingwersen and Järvelin,^[1] pp. 192–194). Salient among the former are:

- *Task dependency*: The perceived work task (or non-job-related daily-life task or interest) situation is seen as the underlying reason for information need development.

- *Role of intermediary*: The role of human intermediaries was originally much in focus but has declined in and after the 1990s; likewise, automatic intermediary systems were in focus in the 1980s, but this focus faded away in the 1990s; currently, end-user behavior and interaction is in focus.
- *Interaction*: This is seen as the central process for cognitive IR; interaction has the purpose to benefit from the cognitive differences between various actors in the IR process; harmonizing such differences is regarded futile.
- *Relevance*: This is seen as objective and subjective, multidimensional, dynamic, and of nonbinary nature.
- *Context*: IR is placed in context in a holistic way: all components/cognitive actors and structures of information seeking and IR are contextual to one another.

CONCEPTUAL MODELS IN INFORMATION RETRIEVAL

There are several different types of models in user-oriented and cognitive IR research. The terminology in the area varies—scholars discuss various models, paradigms, metatheories, etc.—while often meaning the same or a very similar notion: socially shared *ontological* (what is out there to investigate?), *conceptual* (how to name that?), *factual* (what to take as givens?), *epistemological* (how can we possibly know about it?), and *methodological* (how can we learn about it?) assumptions in a research area. The present entry discusses them as *conceptual* models (Ingwersen and Järvelin,^[1] p. 12).

Functions of Conceptual Models

Conceptual models provide the conceptual and methodological tools for formulating hypotheses and theories. Thus, they are, in fact, broader and more fundamental than

Fig. 1 IR research areas.

Source: From Ingwersen and Wormell.^[1]

scientific theories in that they set the preconditions of theory formulation. When they are also seen to represent schools of thought, chronological continuity, or principles, beliefs, and values of the research community, they become paradigms.

The conceptual model of a research area is always constructed—it does not simply lie somewhere out there waiting for discovery. The construction of conceptual models in a research area often requires conceptual and terminological development. This may involve defining concepts better—regarding preciseness, accuracy, simplicity, generality, and suitability for expressing propositions. Moreover, good concepts represent essential features (objects, relationships, events) and classify central phenomena in ways that lead to interesting hypotheses. This means that the concepts should relate to each other explicitly and in systematic and fruitful ways (Ingwersen and Järvelin,^[1] pp. 11–13).

In the following, models are grouped into generic models and relevance models (“Generic Models” and “Relevance Models” sections), process models (“Online Interaction–Process Models” section), models on cognitive structures and actors (“Cognitive Structures and Actors” section), and task-based models (“Task-Based Models” section).

MODELS OF USER-ORIENTED AND COGNITIVE IR

Generic Models

To map out a research area, one needs a model of a broad scope. Often such models are, in addition to being broad, also generic summary models over a large domain. The Ingwersen–Wormell model and Wilson’s model, discussed in the following text, are such examples.

The Ingwersen–Wormell model

The interaction model by Ingwersen and Wormell^[3] (Fig. 1) represents the components and the interactive processes in IR. The right-hand side presents the user’s (or actor’s) problem space, for example, as part of a process of interest fulfillment or problem solving. If not solved by the actor alone, this “problem space” may lead to an information problem or need that results in a request for information, often formulated for an IR system.

In the middle, the intermediary functions consist of the entire system’s capacity to understand and support the information problem of the current actor, as well as the search possibilities and logic of the source system. These functions form part of the professional knowledge of the human intermediary (librarian/information specialist) or may be skillfully adapted to a front end to the system as a search interface, in order to support retrieval. On the left side, components consist of author texts to be

represented through indexing and of IR techniques that determine the behavior of the IR system.

Interaction takes place between an intermediary and an actor having a desire for information, whereby request formulation and reformulation (R) may occur. The query denotes reformulation or transformations (Q) of the request(s) for information, in the form required by the actual IR technique. At search time, the IR technique and actor’s request and query (re)formulation interact.

The model reflects the typical pre-web and pre-PC research situation strongly involving a human intermediary or an interface construct consisting of intermediary knowledge and functionalities—see also the MONSTRAT and Mediator models (“Cognitive Structures and Actors” section). The model points to a number of central variables involved in IR interaction, most of which were studied intensively. The text representation component and processes were the least investigated—yet note the Anomalous State of Knowledge (ASK)-based studies (“Cognitive Structures and Actors” section) and the THOMAS system,^[4] which early on included this aspect.

Wilson’s model

Wilson^[5] summarized the central user-oriented or cognitive research models associated with information behavior studies, including interactive IR. His overall model (Fig. 2) demonstrates the nesting of the central concepts, hereby also showing their contextual nature.

The central idea in Wilson’s model is that interactive IR always takes place in the context of information seeking that again constitutes one of several information behavioral activities. As Wilson saw it, many IR models were basically confined to IR (the Cranfield model of IR) or interactive information retrieval (IIR)—not covering the information-seeking process. A limitation of such models would be—as they contain strong elements of IR systems—that they do not explicitly point to softer seeking processes *not* involving formal information channels. The model points to ideas about which kind of behavioral processes are distinctively

Fig. 2 A nested model of information behavior.

Sources: Modified from Wilson^[5]; Ingwersen and Järvelin.^[1]

not seeking processes, as, for instance, communication and generation. Wilson's model depicted in Fig. 2 contains, as an added feature, also the underlying situational reasons for information (seeking and IIR) behavior: the notions of "daily-life interests" and "work task."

Relevance Models

The concept of relevance has been a difficult issue in information science and IR through the years. It received a lot of attention in the 1960s and 1970s—as reflected in Saracevic's^[6] review. The main orientations in the notion of relevance were found early: on one hand, one may speak about topical relevance and on the other hand, about user-oriented relevance. After a decline of interest in relevance in the 1970s–1980s, there was a revival of interest in the 1990s, producing several models of relevance based on a dynamic, multidimensional, and multigraded view of relevance. Here the models by Saracevic, Cosijn, Wang and Soergel, and Borlund are discussed.

Saracevic's stratified model

Saracevic's stratified model of interaction levels^[7] was inspired by the idea of actors placed in a context—called the "environment." The model (Table 1) served dual purposes: it pointed to three communication levels and led to a revised view of the types of relevance involved in IR. The communication levels consisted of a *surface processing stratum* (light gray) dealing with data processing between sources and interface—based on a query; this stratum is hence concerned with morpholexical and syntactic levels of information processing. The second stratum is the *interactive cognitive communication level* (gray) embracing the processes of perceiving information during human–machine interaction in relation to the perceived need for information. The third stratum is called "situational" (dark gray) and refers to information use with respect to a perceived work task in context. The latter

two strata also rely on semantic and pragmatic levels of information processing.

Saracevic proposed a range of relevance types in IR interaction,^[7] suggesting five increasingly subjective types of relevance: 1) "algorithmic" relevance, which is the basis for the ranked output by the search engine and refers to the statistical and morpholexical relationships between request (or query) and retrieved objects; 2) "topicality" relevance, basically dealing with the aboutness relationship between document contents retrieved and request, as assessed by a person [owing to the human assessment (interpretation), this type of relevance is not objective but rather of subjective, emotional, and intellectual nature]; 3) "pertinence" relevance, which is associated between the nature of retrieved objects and the information need as perceived by the actor at a given point in time; 4) "situational" relevance, corresponding to the relation between the retrieved objects and the work task (or daily-life) situation as perceived by the individual actor; and 5) "emotional/intentional" relevance. This stratified model became later extended to include graded relevance as an additional dimension by Spink, Greisdorf, and Bateman.^[8]

The Cosijn model

Cosijn and Ingwersen^[11] further developed the Saracevic's model. They saw the emotional/intentional type as forming a natural part of *all* the subjective relevance categories;^[2–4] they also replaced it by a "socio-cognitive" relevance category referring to domain, context, and collective situational preferences. The socio-cognitive relevance by Cosijn and Ingwersen is objective and tangible. It signifies situational relevance assessments and interpretations made by *several* cognitive actors, simultaneously (like in a team or program committee) and/or temporally (citations, in links).

Fig. 3 integrates relevance types with the stages of an interactive IR process. Moving from the lower right-hand corner upward signifies awareness and perception of the work task context that influences the information-seeking processes turning into IR interaction and finally algorithmic IR. The opposite move implies feedback from the system and possible request and need modification, as well as the use of information for task performance, influenced by the simultaneous relevance judgments. Automatic query modification takes place in the upper left corner, based on algorithmic relevance assessment. This model suggests hypotheses on relationships between relevance types and criteria, and information-seeking, and retrieval processes and actions.

The Wang–Soergel model

Moving into the details of using information resulting from IIR, Wang and Soergel produced their document

Table 1 The Saracevic stratified model in tabular form

Figure 1. The Saracevic stratified model in tabular form			Information use	
Interaction	Layer	Adaptation		
The diagram illustrates the Saracevic stratified model. It consists of a central column of layers: Environment (dark gray), Situation (dark gray), User knowledge, tasks, etc. (light gray), Query characteristics (light gray), Interface (light gray), Computational resources (light gray), and Informational resources (light gray). To the left of these layers is a vertical double-headed arrow labeled 'Interaction Levels/strata'. To the right of the layers are two vertical double-headed arrows labeled 'Adaptation', one between the top three layers and one between the bottom three layers. To the far right is a vertical double-headed arrow labeled 'Information use'.	Environment	Adaptation	Information use	
	Situation			
	User knowledge, tasks, etc.			
	Query characteristics	Adaptation		
	Interface			
	Computational resources			
	Informational resources

selection framework.^[12] It was based on a longitudinal empirical study of 25 self-selected faculty and graduate students in Agricultural Economics. The framework, Table 2, was also a stage model. It presents in great detail the decision stages by applying 11 relevance criteria and five document value dimensions for the decision to select (and potentially later to use) retrieved documents. In addition, it succeeds in combining the criteria, values, and decisions with so-called document information elements, that is, author-generated document structures and data elements, as well as significant data connected to the “isness” of information objects. These are representations of additional cognitive actors responsible for the being of documents. It supplies highly interesting and novel possibilities of hypothesis generation on relationships between *structured* document *features*, actor knowledge, multiple relevance criteria, and perceived value(s) of documents. It supplements the Cosijn model pinpointing to assessment variables at each point of subjective relevance judgment.

The Borlund model

Borlund summarized and discussed relevance research.^[13] Her model seeks to cover all the relevance types discussed

earlier in an analytical manner, taking into account the temporal dimension too (Fig. 4).

The double circle signifies that more than one actor (assessor or user) may be influenced by the same work task situation, also over time, and thus produce socio-cognitive relevance assessments.^[11] Each actor may dynamically over time perceive the work task differently (CW–CWⁿ) and thus produce new versions of the actor’s information need (N–Nⁿ). Algorithmic relevance (A) takes place in the real world and is objective, whereas intellectual topicality (IT), as Borlund calls “topicality,” and pertinence (P) are seen as subjective manifestations of relevance. IT curves into the actor to signify interpretation activities. The model may in addition point to other relationships and comparisons, for instance, between the real work task and formulated requests and queries or between the task, its fulfillment, and the retrieved objects.

Online Interaction–Process Models

A number of models describe and analyze online searching, mainly in a Boolean real-life searching environment. Models by Fidel and Bates, discussed here, are representative and, owing to their generic nature, also still highly useful in the web IR context. Further, a model by

Kumpulainen is presented as it includes dimensions of searching patterns in heterogeneous information environments. The models focus on the actor's behavior in online interaction, especially on the acts (at various levels of conceptualization) that the actor may choose to implement.

Fidel's models

Fidel and Soergel^[15] developed a comprehensive model on factors affecting online bibliographic retrieval. They classified hundreds of searching variables into seven categories such as the *retrieval setting* (the organization, the status of online searching within it, the actor group), the *actor* (e.g., personality, education, and experience), the *request* (e.g., domain, complexity, and specificity), the

database(s) used for searching (like coverage, structure, and cost), the *search system* (e.g., searching aids and output formats), the *search process* (e.g., interaction with the actor and query formulation), and *search outcome* (recall, precision, and other measures). This model suggests a large number of variables and their possible relationships. The authors also noted that, taken individually, the variables seem to have little influence on the search outcome. This model is abstract and analyzes to some degree the relationships of categories and their proposed variables. It is a specific model for all online (bibliographic) IR—but can easily be usable in web IR environments.

In a range of empirical studies, Fidel investigated the basic dimensions of online searching.^[16–21] She first observed online searchers doing their regular job-related searches. This led to a characterization of *operationalist*

Fig. 4 Types of relevance in a temporal setting.

and *conceptualist searchers* at pre-search, search proper, and post-search stages (Fig. 5). The former tended to use a large range of IR system capabilities in interaction (operational moves), focus on precision, but tended not to modify the specific meaning of requests. On the contrary, the latter tended to map requests into a faceted structure, focus on recall, and to use conceptual moves and thus modify the specific meaning of requests.

Subsequently she analyzed the searchers' moves in interaction that are used to cut down or enlarge, or to move, a search to better target it. Eighteen operational moves and a dozen conceptual moves were identified. The former keep the meaning of a search formulation intact but affect the result size or target, for example, by limiting a search key to an index term field, adding a synonym, or limiting by year of publication or language. The latter changes the conceptual content of a search formulation, for example, by intersecting the formulation with a new conceptual facet and by using broader or narrower index terms.

Finally, Fidel analyzed the searcher's selection of search keys and searching styles during operational online IR. Searching style was found to have a primary effect on retrieval behavior over three dimensions: 1) level of interaction; 2) preference for operational or conceptual moves; and 3) preference for text words or index terms. The *operationalist searcher* prefers to employ operational moves and is less concerned with recall than the *conceptualist* counterpart. The *free-text searcher* prefers to apply text keys and avoids consulting a thesauri. In effect, Fidel's model is a model on the interaction process stages, possible moves, search key selection, and the searching actor's styles.

Bates' berrypicking

Bates^[22,23] classified information search and idea tactics, which were intended for use in teaching and facilitating

searching—seen as an interactive process using a (Boolean) IR system. In all, 29 search tactics in four categories and 17 idea tactics were proposed. The tactics can be used to analyze what happens in a search process and to facilitate further steps in an ongoing process—related to Fidel's moves. The tactics themselves do not contain factors that would connect the search process to its context—for analysis and explanation.

Later, Bates^[24] criticizes the narrow view of IR (traditional online and laboratory noninteractive) as searching based on a stable topical need. To Bates, real-life IIR was exploratory like *berry picking*. She developed berry picking as a principle for actor behavior that became very influential during the 1990s. The principle entails that each new piece of information that the actors encounter provides them potentially with new ideas and direction to follow through interaction, and consequently a new conception of their information need. At each stage of the search, the actor may identify useful information items leading the actor onward. Therefore the actor's requests and queries have several versions, which may change owing to the system feedback and actor's interpretation. Thus, we may here not simply talk of alternative versions of the request but also of more profound modifications. During the process, the actor may also repeat a query or revisit some earlier retrieved objects due to knowledge processes and cognition. Bates called this mode of retrieval an "evolving search." The information need situation is hence not satisfied by a single final retrieved set, but by a series of selections on the road, so to speak, of individual (elements of) information objects. Bates suggested several capabilities that might support the actors better in their various information-seeking strategies than the IR systems of that time. In effect, Bates' model is an abstract descriptive model of IR interaction.

Search trails

Kumpulainen^[25] presented a task-based approach to model search behavior patterns. Influenced by earlier search process models reflecting people's real-world search behavior (e.g., Fidel,^[18] Bates),^[22] Kumpulainen's model targets a need to understand search behavior across several search systems. Search patterns across information systems are named "trails" and defined as follows: "A trail is a manual integration pattern, which includes one or more sequences of queries, and which may spread over several search systems containing heterogeneous information types" (Kumpulainen,^[25] p. 857). Based on a qualitative study within the domain of molecular medicine, Kumpulainen empirically identified and modeled five different trail types: 1) *single* trails where only one query and one system is involved; 2) a *list* formed by similar types of queries submitted into a single system; 3) a *chain* formed by searches to several systems in a chain-like manner; 4) a *branch* formed by a search to several systems, which can

be concurrent and are unordered; and 5) a *berry-picking* trail formed by an exploratory search behavior and a dynamic information need. The strength of the modeled trail types is that they reflect a real-world heterogeneous information environment where actors might submit several queries across different search systems.

Cognitive Structures and Actors

The cognitive approach to IR produced several models of cognitive structures and actors and their interaction. The seminal ASK model by Belkin and colleagues and the MONSTRAT and Mediator models by Belkin and colleagues and Ingwersen are discussed in the following text. The latter were part of the active development of intelligent intermediary systems for IR in the 1980s and early 1990s.

The ASK model

Belkin^[26–28] developed the ASK hypothesis and a concept of information for information science. The model in Table 3 is very general and abstract. Initially, it signified the cognitive communication system of information science;^[26] later on, it mapped the IR interaction at the two most important levels of cognition: 1) the cognitive and 2) the linguistic (surface) levels of communication.^[27] In contrast to earlier and contemporary common beliefs in user studies and laboratory IR that an information need “jumps out of the blue”—and is context free—the ASK hypothesis attempted to explain *why* information need situations occur. The fundamental reason behind an ASK was the problematic situation the actor was facing if the actor could not manage to fulfill an issue or solve a problem at hand. In addition, ASK implies that the ensuing information (search) situation is dynamic, and needs and requests may change with variation in cognition over retrieval session time. At the surface level of a message, we have the texts (signs), with which the recipient interacts. If the recipient perceives the signs, information is communicated at the cognitive level, and the ASK is thus under change. This model led to more detailed cognitive communication models for information transfer, for example, by Ingwersen,^[29] p. 33, and further to the “bag” models for interaction (Ingwersen and Järvelin,^[1] p. 33, p. 50). Also, the ASK model led, through several empirical studies, to the MONSTRAT model by Belkin, Seeger, and Wersig.^[30]

Table 4 Functions of the MONSTRAT model

Name of function	Description
Dialogue mode (DM)	Determine appropriate dialogue type for situation, e.g., natural language, menu, form-based
Problem state (PS)	Determine position of user in problem treatment process, e.g., formulating problem for a paper (student)
Problem mode (PM)	Determine appropriate mechanism capability, e.g., reference IR or referral to institutions and persons
User model (UM)	Generate description of user type, goals, beliefs, e.g., graduate student, thesis or paper, R&D person, etc.
Problem description (PD)	Generate description of problem type, tonic, structure, environment, wanted attributes in texts (doc.type)
Retrieval strategy (RS)	Choose and apply appropriate retrieval strategies to knowledge resource, e.g., exact match, extended Boolean
Response generator (RG)	Determine propositional structure of response to user appropriate to situation, e.g., list document titles
Input analyst (IA)	Convert input from user into structures usable by functional experts, e.g., parse NL request text, note option selection
Output generator (OG)	Convert propositional response to form appropriate to user and situation, e.g., display new menu, rank titles
Explanation (EX)	Describe mechanism operation, capabilities, etc. to user as appropriate

Source: Adapted from Belkin et al.,^[31] p. 399.

The MONSTRAT and Mediator models

Belkin and colleagues followed up the work on the ASK hypothesis by a functional discourse analysis of pre-search client–librarian interactions. This led to an analysis scheme consisting of 10 categories and a number of sub-categories (Table 4). The metacategories of the scheme correspond to the intermediary functions that constitute the analytic MONSTRAT Model (*modular functions based on natural information processes for strategic problem treatments*) developed by Belkin, Seeger, and Wersig,^[30] which, again, was the basis of the active development of intelligent intermediary systems in the 1980s.^[31]

Probably owing to its foundation in the analysis of search interviews, the model encompasses the functionality of an interface for interactive IR but emphasizes strongly the human actor side. Only the retrieval strategy (RS), response generator (RG), and the output generator (OG) functionalities are associated with underlying IR engines and/or information sources. Hence, intelligent systems built on MONSTRAT (and similar expert system architectures) become stand-alone systems. The underlying document collection and the retrieval engine is

integrated with the interface and hence not really modeled by MONSTRAT. This led Ingwersen to propose an extension to MONSTRAT, the Mediator model.^[29] That model is based on 13 major functionalities and more than 50 minor ones. A rather symmetric cognitive view of the information transfer processes and knowledge types involved is reflected in the principle of the model. According to the Mediator model, an intermediary mechanism must possess knowledge of the underlying *system setting*, including knowledge of documents, representation algorithms, and database structures, and the *IR processes*, that is, source selection and strategies. Symmetrically, it should contain knowledge of users (human actors) and their potential preferences and expectations, IR know-how, and domain knowledge (a preconditioned *user model*) and be able to carry out *actual user and request model building* during retrieval, based on the user model. In order to be operational, it must consist of knowledge concerned with *domains and domain tasks* (emotional/conceptual structures) and have *intentionality*, that is, means to store and use expectations based on past experiences and are able to plan its actions. Bates^[32] discusses critically the desirable level of automatic support in IR interfaces.

Ingwersen's interactive IR model

A more symmetric perspective of IR interaction and transfer in general, centering on the interface–actor interaction, is observable in the contextual models by Ingwersen (Ingwersen;^[29] extended in),^[33] which further explore the IR processes and components originally depicted in Fig. 1. Ingwersen^[29,33] modeled IR interaction by incorporating the socio-organizational environment (context) of the current actor. That context includes the scientific or professional domain(s) with information preferences, strategies, and work tasks that influence the perception of the actor. The model also emphasized polyrepresentation in documents, in search engines, and in the cognitive space of searchers at any point in time. Further, the model introduced the influence of context on the information and system spaces and the social interaction between socio-organizational factors and actors. It is in this model that cognitive actors appear for the first time, signified by the notion of “models” in each component. However, the model did not explicitly demonstrate the relevance and information use dimensions of interactive IR. The principle of polyrepresentation is derived from the cognitive models and is further analyzed.^[34]

Task-Based Models

Toward the end of the 1990s, the cognitive models of IR increasingly developed into explicitly task-based models. Vakkari^[35,36] extended the Kuhlthau model of information seeking into the field of task-based IR. Ingwersen

and Järvelin^[1] further developed Ingwersen's model (“Cognitive Structures and Actors” section) into a genuine multidimensional research framework for IR and seeking studies, Xie's model^[37] suggested how to integrate macro- and microlevels of interactive IR, and finally, Järvelin and colleagues^[38] proposed and modeled an evaluation framework encompassing the complexity of task-based information interaction in practice.

Vakkari's model

Vakkari^[35,36] extended the Kuhlthau model of information seeking^[39] in the field of task-based IR, based on a series of longitudinal empirical studies (Fig. 6). His model explicates the relationships of task performance stages, kinds of information sought and its potential contribution, factors related to searching, and relevance assessments and information use. In addition to the analysis explicated by the model, Vakkari showed that phases in task performance were systematically connected to the information searched for, and the search tactics and usefulness of the information retrieved.

The strengths of the model include the following: 1) There is a clear-cut and necessary distinction between domain knowledge associated with (work) task performance, and IR knowledge. 2) Work task stages and the use of information in work task performance are clearly separated from search task execution. The end product of the search task that of relevance assessments bridges back to the use of information in task execution. 3) There exists the concept of “expected contribution,” which refers to the experience gained by the actor in temporal sense.

The Ingwersen–Järvelin integrated model

Ingwersen and Järvelin,^[1] (p. 261, 274) further developed and extended the cognitive and task-based IR models to a comprehensive model of information seeking and retrieval (IS&R) (Fig. 7). Numbers on the model basically deal with processes of interaction (1–4) such as social interaction (1) or refer to different kinds of generation and transformation of cognition or cognitive influence (5–8). They are explained in the following text in more detail.

The model (Fig. 7) emphasizes the information processes that are executed during IS&R in context over time: First, processes of social interaction (1) are found between the actor(s) and their past and present sociocultural or organizational context. Social interaction may instigate IS&R activities, but may also form part of their fulfillment. Second, information interaction also takes place between the cognitive actor(s) and the cognitive manifestations embedded in the IT, and the existing information objects via interfaces (2/3). The latter two components interact vertically (4) and constitute the core of an information system. This interaction only takes place at the linguistic sign level. Third, cognitive and emotional

Fig. 6 Stages in work and search task performance. Arrows represent the direction of impact.

Source: Vakkari.^[36]

transformations and generation of potential information may occur as required by the individual actor (5/7), as well as from the social, cultural, or organizational context toward the IT and information object components (6/8) *over time*. This implies a steady influence on the information behavior of other actors—and hence on the cognitive–emotional structures representing them. The impact entails that actors may collaborate in teams—like in collaborative IR(CIR)—and collectively adapt to their surroundings.

The model emphasizes that all the participating cognitive structures are in context of all other cognitive components of the model. Hence, there exists a mutual dependency of context and actor or component, including intracomponent structures. For instance, images in objects naturally act as context for the surrounding text—and *vice versa*. At a more detailed level, depicted inside the nodes, the model develops further into the complexity of cognitive structures associated with its five components. Each structure may take a different form depending on the type of information objects, media, and domain.

The framework suggests *empirical variables* that can be combined for research, and from which one may make hypotheses and predictions of potential solutions, for instance, for IR systems development or evaluation

(Ingwersen and Järvelin,^[1] pp. 274–275). A more complete set of research variables categorized into nine dimensions extracted from this model, as well as suggestions for research designs, are discussed in Ingwersen and Järvelin,^[1] pp. 313–376.

Xie's planned-situational interactive IR model

With an aim to integrate macro- and microlevels of interactive IR, Xie^[37] proposed in 2008 the planned-situational interactive IR model (Fig. 8). The model builds on earlier interactive IR models, empirical research, the planned model approach from cognitive science, and theory of situated action derived from social science. At the microlevel, the model illustrates the determining factors of information-seeking strategies. Thus, it presents the relationship between 1) levels of actor goals and tasks including dimensions of work/search tasks, 2) actor's personal information infrastructure, and 3) information-seeking strategies constituted by interactive intentions and retrieval tactics. Further, the model illustrates how plans and situations codetermine interactive intentions and retrieval tactics in the information-seeking process (Xie,^[37] p. 236) and thus argues that information-seeking

Fig. 7 Cognitive framework of interactive information seeking, retrieval, and behavioral processes.

Source: Ingwersen and Järvelin.^[1]

Fig. 8 Planned-situational interactive IR model.

Source: From Xie.^[37]

strategies can be seen as a product of plans and situations. In contrast to earlier models by Xie, the planned-situational interactive IR model includes the social-organizational context and actor-system interaction at the macrolevel. The model can therefore be seen as a further development of the Ingwersen-Järvelin integrated model^[1] illustrating how to integrate microlevel elements of interactive IR process to the macrolevel processes. This is the main strength of the model in combination with the comprehensive explanation of how the model relates to and builds upon earlier user-oriented and cognitive IR models (Ingwersen and Järvelin,^[1] Bates,^[22,23] Vakkari,^[35] Kuhlthau,^[39] Ellis^[46]).

Task-based information interaction evaluation framework

Järvelin and colleagues^[38] pointed to the need for a comprehensive and systematic evaluation framework encompassing the complexity of task-based information interaction in practice, that is, involving actors, contextual factors, and highly interactive search situations and focusing on how interactive IR improves human task performance—in contrast to taking a traditional IR approach measuring ranking of relevant documents. Accordingly, the authors modeled an overall evaluation framework illustrating the components in a task-based information interaction (Fig. 9). Building on program theory,^[40] the evaluation framework aims to generate program theories upon which task-based information interaction evaluation can be built. The evaluation framework consists of 1) *inputs* of contextual factors, perceived task, and actor; 2) *activities* undertaken during the process, namely, task planning and assessment, searching information items, selecting items, working with items, and synthesizing and reporting; 3) immediate *outputs* such as documents or presentations; and 4) possible *outcomes* measuring learning or task outcomes. Järvelin and colleagues describe in detail how the framework supports the evaluation of each of the individual activities using their specific program theories. A main strength of the evaluation framework is

that it focuses on explaining causal relationships between program components *and* explaining how components are related to each other. Accordingly, evaluation is not limited to, for example, performance of the individual tool, but aims to encompass the complexity of humans performing tasks with tools in contexts.

CONCLUSION

In contrast to the Cranfield model of IR, there must exist several models for information seeking and interactive IR that complement one another. Which one to use is dependent on the kind of IS&R processes one wishes to study, in particular when involving seeking actors. The latter models constitute a form and level of complexity not dealt with in system-driven information research and models.

The future may see the development of models and frameworks that increasingly encompass (task-based) context. Here it seems important to stress not only that socio-cultural and organizational contexts are central to information interaction but that the system, network, and information space—the systemic context—are vital for understanding such processes. Even relevant infrastructural features, like bandwidth or legislation, may necessarily form part of such contextual models.

Venezuela: Libraries and Librarianship

Juan D. Machin-Mastromatteo

Renny Granda

Universidad Central de Venezuela, Caracas, Venezuela

Abstract

This entry presents a general, brief, and nonexhaustive overview on the origin, development, and the crises of Venezuelan libraries and librarianship. The first section offers an historical background on the first Venezuelan libraries, highlighting the origin of the National Library, together with some of the most important characters of this early history. Moreover, it narrates milestones such as the first Law of Libraries of the country, the celebration of librarian's day, and the *Caracas Declaration*. The second section briefly presents some current types and examples of Venezuelan libraries, such as academic, public, special, digital, and repositories. The third section discusses the development of Venezuelan librarianship, the related professional degree and professional education, including the main schools, programs, and curricula. The fourth section summarizes the current crisis faced by libraries and the profession itself. Finally, some brief comments are offered as a conclusion.

The university cannot be neutral in the historical debate between democracy and dictatorship.

—Rómulo Betancourt (1959)

A National Information Policy has more possibilities of receiving significant government attention if it were supported by information professionals.

—Iraset Páez Urdaneta, *In Information for the development of Latin America* (1990)

Manuel Segundo Sánchez showed, in his patient and quiet labor, that there was a liberating force of the spirit, that there was an escape and an alibi to arm the resistance, which was no other than mankind's culture, in front of which dictators and warlords in power would never understand their unassailable argument.

—Karl Krispin (2007)

Public Libraries (NSPL) was established between 1970 and 1980, and the base of the pyramid is comprised by the academic libraries, which are located throughout the main cities of the country. Some special and institutional libraries are noteworthy, but they are isolated cases. The National Library (NL) is the main library institution in the country; public policies of the sector and the planning of the NSPL stem from it. However, this institutional figure has not been enough to carry out large projects and a responsible and stable professional scholarship. Within a complex political, social, economic, and cultural context, Venezuelan libraries claim to be vindicated.

HISTORICAL BACKGROUND

Historians set the arrival of books to Venezuela between the sixteenth and seventeenth centuries. From 1600, the presence of books starts to be notorious in colonial time cities.^[1] Books arriving from Spain made possible to start developing the first libraries with these manuscripts or printed books, from approximates of 25–500 volumes, and in no way they represented the ideal institutions for the custody, preservation, and classification of collections, which started to appear from the nineteenth century.^[1] This section summarizes the first Venezuelan libraries, the first printed publications, the origin of the NL, as well as the most important figures of this early stage of Venezuelan libraries and librarianship, such as the first bibliographers and the leading roles of Rómulo and Virginia Betancourt. Moreover, some notable developments are presented, such as the first and only law of libraries in the

INTRODUCTION

The topic of libraries and librarianship in Venezuela is challenging. Over the last years, this sector has had the same results as any aspect of national life: fragmented, dispersed, confused, hermetic, and uncertain. In this Latin American country, librarianship is an undervalued profession; it is not taken into account, even by the academia. Only two universities offer undergraduate programs on librarianship, and they keep a technical paradigm tied to archival science. In general, library infrastructure is scarce given the national population of over 30 million inhabitants. The development of school libraries is practically inexistent, the National System of

country, the events leading to the commemoration of the librarian and archivist day, and the *Caracas Declaration*.

First Steps and the Establishing of the National Library

The first known colonial library belonged to the Convent of Our Lady of Salceda in St. Anne of Coro, it was established by the end of the sixteenth century, and according to chroniclers, historians, and librarians, it comprised 300 volumes which were sometimes lent to the city's inhabitants.^[2] Libraries from the seventeenth and eighteenth centuries were mainly private and belonged to national aristocrats, destined to family use, as well as those belonging to the clergy.^[1]

In 1691, there was a notable decree by the provincial of the Franciscan order, Diego de Hoces, which indicated how convent libraries should function and it called for the appointment of a librarian to be in charge of the loan service for 2 hours each day and to maintain a written log for this service. This is the earliest registered presence of a librarian in Venezuela. A century later, in 1790, the first known librarian appeared: Father Cristóbal de Quesada, who also taught Latin and grammar to Andrés Bello, and worked at the library of the Convent of the Mercy in Caracas.^[1] At the time of the Independence (nineteenth century), there were two key moments: the first Venezuelan periodical, the weekly *Gazette of Caracas*, was printed in 1808; and in 1810, the first book was printed, the *Manual Calendar and Universal Guide of Foreigners in Venezuela* for the year of 1810. Both publications were prepared in the press owned by Gallagher and Lamb.^[2] Furthermore, the idea of a new type of library which would allow readers access emerges: the public library (PL). Its role was also intended as a tool for public instruction after the date of the Declaration of Independence, on April 19, 1810.^[1] This idea was published in a printed sheet that began to circulate by the beginning of 1811, *Thinking of a public library in Caracas*, signed by Juan Germán Roscio and possibly written by Francisco Javier Ustáriz,^[1,2] both signatories of the *Declaration of Independence*. It was the first intention of a project to create a public library, which was deferred by the Independence War. Even so, during the period of the *War till Death* (1814), the Liberator Simón Bolívar commissioned the collecting of books and ordered the formation of a public library.^[2]

From 1830, the idea of creating a NL appears. Particularly in 1831, the Interior Secretary Antonio Leocadio Guzmán manifested the need of merging the convent libraries and books dispersed throughout government offices.^[1] Diverse decrees with the intention of creating the NL were issued in the subsequent years, but these initiatives were not so successful. Some of such decrees were 1) by president José Antonio Páez in 1833, pointed out by some scholars as the date of the foundation of the

NL;^[3,4] 2) by president José Tadeo Monagas in 1850; 3) a decree from 1852, which also assigned a budget to the NL; 4) by president Julián Castro in 1858, which appointed several directors and organizational changes; and 5) by president José Ruperto Monagas, in 1869, which presented improvements for the NL in areas such as staff salary and service regulations. Finally, in 1870, it was during the government of the president Antonio Guzmán Blanco that a solid base for the functioning of the NL was established.^[1] The first statistical report of the NL collection appeared in 1873, being comprised by 5862 volumes. In 1874, Guzmán stipulated that the collections of the convent libraries were to be delivered to the Universidad Central de Venezuela (UCV), the first and largest public university. These collections were to be incorporated to the NL, which was located at the time in the university campus. In 1875, Adolfo Enrns publishes the *Catalog of the Library of the University of Caracas*, the first printed catalog of the NL and of Venezuelan bibliography. Ernst directed the NL from 1876 to 1889. In 1892, the library separated from the UCV and in the following year it was moved to another location through a decree by the president Joaquín Crespo.^[1]

At the beginning of the twentieth century, the situation of the country was critical due to the Civil War. When Juan Vicente Gómez got into power in 1908, he decided to appoint the construction of a dedicated headquarter for the NL, so in 1910, he commissioned architect Alejandro Chataing with this construction. This new headquarter was built next to the UCV and it was inaugurated in 1911, coinciding with the commemoration of the Centennial of the Independence. In 1937, after the end of the dictatorship, a stage of modernization of the NL was started by its director Enrique Planchart. From 1950 toward the end of the twentieth century, the library had five directors; the most important of them took office in 1974 and transformed the institution into an autonomous organization, among other improvements. In 1960, the Book Bank was created as a nonprofit organization, thereby starting a new vision of library services. In 1974, Venezuela became the first Latin American country to have policies for the creation of the NSPL.^[1] The current headquarter of the NL, designed by José Tomás Sanabria, consists of a building with a total size of 80,000 m², which was constructed from 1981 and began to function in 1989.^[2]

The First Bibliographers

In this brief historical journey, it is relevant to mention the first characters that conducted activities related to this discipline. In the first place, there were the fathers of Venezuelan bibliography, Arístides Rojas, Adolfo Ernst, Juan Piñango Ordoñez, Adolfo Fryndesberg, and Manuel Segundo Sánchez. The latter was a true pioneer in setting the bases of Venezuelan bibliographic research, by

establishing the foundations for the development of this discipline in Venezuela, and from 1913 to 1920 he directed the NL. Among his most important works were *Venezuelan Bibliography* (1914), which includes nearly 1500 records and until now it is considered the only work of its kind; the *Venezuelan Library* (1917), *Bibliographic Yearbook* (1917), which the NL took as a model from 1942 in order to systematically compile its own yearbooks; and the *Bibliography of Bibliographic Indexes Related to Venezuela* (1939). He also conducted research on the printing press in Venezuela and created the denomination of *Venezuelan incunabula* for every Venezuelan publication printed from 1808 (year of the first printed publication) and 1821 (Battle of Carabobo). Curiously, Walter Lichtenstein acquired the private library of Sánchez and his books ended up in universities of the United States such as Harvard, Northwestern, and the University of Chicago. Finally, there is the figure of Pedro Grases, compiler of the fundamental writings of Venezuelan intellectuals and statesmen. His most important works are related to the history of the printing press in Venezuela, an inventory of printings of the period between 1808 and 1812, the trajectory of the *Gazette of Caracas* from 1808 to 1822, the Angostura printings of 1817–1822, the *Venezuelan Constitution* of 1811, his bibliographic research on various subjects and profound reflections on Venezuelan bibliographic research.^[5]

Rómulo and Virginia Betancourt

Rómulo Betancourt was the first president of the Venezuelan democracy (1959–1964), he belonged to the Generation of 1928, a group of student leaders which organized the first popular manifestation against the dictatorship of Juan Vicente Gómez (1908–1935). Being a strong opponent of the Gómez regime, he lived a part of those years in exile. Between 1931 and 1935 he lived in Costa Rica, where he started his ideological journeys throughout Latin America. In those years, he worked at the National Library of Costa Rica, taking advantage for advancing and deepening his reading of works such as the 15 volumes of the *Contemporary History of Venezuela* by González Guinán, resulting in his writing of a magnificent summary.^[6] Betancourt was a militant in diverse clandestine political organizations such as the Venezuelan Communist Party and the National Democratic Party. The latter was the predecessor of the political party Democratic Action (AD), founded in 1941 by Betancourt and other Venezuelan left-wing leaders. Betancourt converted a country of warlords and militaries into one of a civil society and republican institutions.^[7] Because of his political views, he was eternally pursued, but despite this persecution and his strong dissident activities he never stopped reading, studying, writing, and publishing journalistic articles, booklets, and books.^[6] His daughter, Virginia Betancourt, will always be appreciated by the educated and democratic Venezuela for her efforts as the director of the NL

between 1974 and 1999, her contribution in the founding of the Book Bank in 1960, and her labor in preserving and classifying her father's personal archive.^[6] During her administration of the NL, he was responsible for establishing the autonomous character of the institution, creating the NSPL, and promoting the Law of Libraries of 1977. Additionally, she encouraged professional meetings and of Latin American integration, such as the one which originated the *Caracas Declaration*. She also participated in the creation of the Association of Ibero-American National Libraries (ABINIA) and her labor made her worthy of the International Federation of Library Associations and Institutions (IFLA) Medal in 2005.

Law of Libraries (1977)

The National Library Autonomous Institute and Library Services (NLAILS) Law^[8] created the figure of the NLAILS from the NL and was the basis for the creation of the NSPL. It was during the era of the discourses about systems, networks, and library management, besides the modernization and transformation of the NL. Legislators and leaders took the advantage of this opportunity to start building the library network throughout the country. With this law, Venezuela stepped forward into the vanguard of the library movement in Latin America, being the third country of the region to create a law of this kind,^[9] which was even considered a model for some library movements in Latin America.^[10]

The NLAILS Law is still in effect, as no new legislation has been passed, despite the fact that it is obsolete and it does not develop the particular area of public libraries. The law is now obsolete because it is antiquated and inadequate given the current circumstances it must govern. It was passed more than 30 years ago, when another constitution ruled the country's destiny, thus overpassing the limits of Venezuela's legal reality. The current constitution of 1999 brought significant changes in every institutional area, mainly materialized through different legal reforms made by the new parliament and especially with legislation through presidential decrees. The NLAILS Law is a *survivor* of that time of major legal reforms. In consequence of the mentioned changes, this Law stopped being useful in its area of application, and nowadays it is officially mentioned exclusively when the president makes changes in the direction of the NL.

Librarian and Archivist's Day, One Date and Three Motives (1982)

The National Librarian and Archivist's Day is celebrated every July 27. This date was chosen as the most iconic for the profession for three reasons. First, July 27, 1945 is recorded as the date of death of Manuel Segundo Sánchez. Second, July 27, 1950 corresponds to the graduation of the first cohort of library and archives professionals from the UCV. The third event happened on July 27, 1977 with the

enactment of the *NLAIS Law*.^[8] Considering these events, on July 23, 1982 the Presidential Decree N° 1.564 was published in the Official Gazette of the Republic of Venezuela N° 32,522, declaring July 27 as the *National Librarian and Archivist's Day*. The document states:

the activities of Library and Archives professionals constitute factors of progress and development for the country, because they fulfill support to education, research, and to the development of science and technology through libraries, archives and information and documentation centers, hence it is fair to recognize their function within the Venezuelan society (p. 245827).^[11]

Caracas Declaration (1982)

The *Caracas Declaration for the Public Library as a factor of development and instrument of social change in Latin America and the Caribbean* was the product of the consensus between experts from 30 countries, that was reached during the *Regional Meeting on the Current State and Development Strategies for the Development Public Library Services in Latin America and the Caribbean*, during October 25–29, 1982. *The Declaration* is the first and most important technical-normative document on PL of the region because it allowed pushing the library movement in Latin America and the Caribbean (LAC).

The Declaration was a regional agreement celebrated in the Venezuelan capital and supported by the United Nations Educational, Scientific and Cultural Organization (UNESCO), the Regional Center for the Promotion of the Book in Latin America and the Caribbean (CERLALC), IFLA, and the Venezuelan NLAIS. *The Declaration* contains the shared visions of the region's professionals at an historical moment: one which opened the door to wider views of social reality, democratic life, and regional integration. Hence, one of the first aspects it mentions is the support to the main principles stated in the UNESCO Public Library Manifesto of 1972. From these principles, the main needs of the region were compared and they were adapted to LAC reality in order to adopt them.

The first part of *The Declaration* enumerates eight principles for a PL of the region, in order to assume the commitment toward development, democracy, and social change in LAC. These principles “express the will of a library majority on what the public library should be in our countries.”^[12] These are summarized as follows:

1. Ensure free access to information which must be broad, current, and representative of the sum of different thoughts, in various formats.
2. Stimulate people's participation in national life, enhancing the role of the library as a facilitator of social change and participation in democratic life.
3. Promote the understanding, dissemination, and defense of national indigenous and minority culture to assert

cultural identity and the recognition and respect toward other cultures.

4. Promote the formation of critical, selective, and creative readers through reading, thus training each individual to play an active role in society.
5. Support lifelong learning, eradicating illiteracy, and supporting services for children, teenagers, neo-readers, and disabled readers, both socially and physically.
6. Serve as information and communication centers for the community.
7. Develop national library services.
8. Support an economically strong and culturally independent national and regional editorial industry.^[13]

The second part refers to the basic conditions for the development of PL in LAC, conforming a vision closer and more real regarding the state of the LAC library, stating the true needs or shortcomings, mainly institutional, which prevented (and in some cases, still prevent) the improvement of services in the region. *The Declaration* states the need of a legal framework to regulate the functions of the PL, contemplating State obligation to offer library services, a national coordination, a system of services, normalization of technical processes, strategies to train human resources, and the sustainable endowment of services. It highlights the role of the State “regarding its functioning and development, and emphasizing the need of the libraries to be included in the development plans of each country, in pointing the State obligation to offer public library services and assigning them sufficient yearly budget for their development” (p. 17).^[14] Moreover, issues such as “to stimulate citizen participation in democratic life” (p. 16)^[10] started to be taken into account.

VENEZUELAN LIBRARIES

The national library infrastructure is currently scarce, given a population of over 30 million inhabitants. Regardless, this section mentions the main libraries: academic, including university and school libraries; the dense network of public libraries and their variations; special libraries supporting the labor of both the private and public sectors; institutional and governmental libraries; and lastly some experiences in digital libraries and repositories.

Academic Libraries

Venezuelan academic libraries include university and school libraries. In public and private universities, there are libraries which fundamentally support professional development and research. The most relevant from public universities are those of Universidad Central de Venezuela, Universidad Simón Bolívar, Universidad de Los

Andes, Universidad de Carabobo, Universidad del Zulia, Universidad de Oriente, and Universidad Nacional Abierta. The most relevant from private universities are those of Universidad Católica Andrés Bello, Universidad Metropolitana, and Universidad Santa María. The main national universities also count with specialized academic libraries according to the faculty or field of knowledge to which they dedicate. School libraries can be found in private institutions but especially in public schools. The responsibility of the State in the conformation of a public school library system rests in the Ministry of Education. In the mid-1980s, there were nearly 1700 school libraries dependent from the mentioned governmental office.^[1]

Public Libraries

The NLAILS is the governing body of the NSPL, and it was inspired by both the *UNESCO Public Library Manifesto* and the *Caracas Declaration*.^[4] The system is comprised by 727 libraries nationwide, organized in 24 state library networks with a total capacity for approximately 38,229 readers, 3687 of them are located in the capital city of Caracas.^[15] Despite these figures, some of its weaknesses are related to the lack of clear policies, technological infrastructure, and an inadequate library staff selection, which in general is neither professional nor trained for such functions.^[4] Regarding statistics, 88% of PL users are students, with an average age of 20 years, and 71% of them study in public institutions. Only 12% of the total users do not study and their average age is 37 years, from this percentage 75% of them are employed.^[15] Part of the explanation behind these figures is that in many cases PLs fulfill the roles or alleviate the lack of school libraries in many sectors throughout the country.

Among the PL, one of the most emblematic is the Book Bank because it was established in 1960, before the NLAILS Law was even drafted, but still it started to provide the basic framework to start developing a network of school and public libraries, first in Caracas and then in other regions of the country. The Book Bank is the “depository of a valuable collection comprised by books for children and teenagers, specialized literature on these literary genres, documental records, periodicals, and texts related to the book and reading promotion” (p. 25).^[3] The Book Bank researches, experiments, innovates, and proposes guidelines for reading promotion and also carries out diverse cultural activities that are not necessarily related to reading.

Special Libraries

The Marcel Roche Library of the Venezuelan Institute of Scientific Research (IVIC) might be the most relevant special library of the country and because it is subordinated to the Ministry of Science, Technology and

Innovation, it is one of the few libraries that can afford and acquire academic databases and scientific journals, given the currency exchange control imposed by the government since 2003. Other notable special libraries are those from each of the National Academies: Language, History, Medicine, Political, Economic, and Social Sciences; Physical, Natural and Mathematical Sciences; as well as the Ernesto Peltzer Library of the Central Bank; the libraries of the Supreme Court of Justice, National Assembly, Attorney General; those in the museums of Natural Sciences, Fine Arts, and Contemporary Arts; the library of the Rómulo Gallegos Center of Latin-American Studies; and those within some foundations, such as the *Rojas Astudillo*, *Pedro Manuel Arcaya*, *John Boulton*, *Vicente Lecuna*, *Humboldt*, *La Salle*, *Centro Venezolano Americano*, among many others.^[1]

Digital Libraries and Repositories

Regarding digital libraries, the Venezuelan experiences have been incipient. The closest related cases are repertoires of specialized information, such as the *Scientific, Humanistic and Technological Information System* of the UCV, university digital journals and some repositories such as: *National Repository of Open Source Software*, *Intellectual Production Repository Universidad Centrocidental Lisandro Alvarado*, *SABER UCV*, *SABER Universidad de los Andes (ULA)*, *Institutional Repository Universidad de Oriente*, *Institutional Repository Universidad Pedagógica Experimental Libertador*, and *Intellectual Production Universidad Simón Bolívar*. Finally, there is the repository *Metadatum*, which aims to group all the academic repositories of the country that are using the OAI-PMH protocol, and to serve as a metasearch engine.

Although there are many repositories in the country's main universities, the first and only institutional open access mandate dates from 2009 and corresponds to the ULA. This consists in preserving the following documents in institutional repositories: 1) theses, 2) research products funded by the Scientific, Humanistic and Technological Development Council, and 3) all University publications.^[16] Despite this scenario, it is important to point out that Venezuela has the sixth place in number of publications indexed in the Network of Scientific Journals from Latin America and the Caribbean, Spain and Portugal (Redalyc), with a total of 54 quality scientific journals, in open access.^[17]

VENEZUELAN LIBRARIANSHIP

There are two Venezuelan traditional Library schools: the Schools of Libraries and Archives of the Universidad Central de Venezuela (EBA-UCV) and its counterpart in the Universidad del Zulia (EBA-LUZ). The UCV is

located in Caracas, the capital city. It was founded in 1721, and it is among the oldest universities in the occidental hemisphere. This university has been the alma mater of many notable Venezuelan scientists, humanists, intellectuals, and presidents. Its current location, the University City of Caracas was built between 1940 and 1960, it was designed by Carlos Raúl Villanueva, with the collaborations of avant-garde artists from the era, and in 2000 it was declared a World Heritage Site by the UNESCO. The EBA-UCV was founded in 1948, and it offers two 5-year bachelor programs, one in library science and the other in archival science. It also offers two master programs: *Management of Information Networks* and *Information and Communication for Development*.

The EBA-LUZ was created in 1962, and it offers the same bachelor programs together with a master in *Information Sciences*. Other universities with more recent academic options are the Universidad de Carabobo, centering on documental certification courses and bachelors; the Universidad Católica Andrés Bello, with a master on *Information Systems*; and the Universidad Yacambú, with a bachelor in *Information and Documentation*. Sadly, there are no doctoral options in the field, resulting in a few doctors with LIS PhDs obtained in other countries and the majority of doctors with a LIS background have obtained PhDs in education, sociology, social sciences, among other disciplines. For the year 2001, there were a total of 3490 LIS professionals registered in the country, nearly 1900 of them were women.^[18]

Origin of the Professional Degree (1950)

The period between February and July 1950 saw the definition of the university degree conferred on the first library and archives professionals of the country. The first director of the EBA-UCV, José Fabbiani Ruiz, manifested his unrest on the matter on February 4, proposing the title of *cataloger-librarian*. Just a month before the graduation of the first cohort of students, in the Assembly on June 26, Fabbiani argued that even if the previously mentioned title was approved in a previous session, the students, director, and teachers of the School thought that the alternative title of *librarianship technician* was more adequate. That was mainly because the title of *catalogers* would presumably prevent them from directing a library, being necessary to obtain a more general and positive title, one that would be a promise and not a menace, according to Fabbiani. The ensuing discussion had interventions from professors Acosta Saignes, Olivares Figueroa, Oliver, Rosenblat, Granell, the Faculty Dean Casanovas, and Fabbiani himself. Finally, several titles were proposed: *library technician*, *library technique graduate*, *library assistant*, *library auxiliary*, and *librarianship technician*. After some deliberations a voting took place, the winning alternative was the one proposed by the School. Hence, on July 27, 1950,

the first *Librarianship Technicians* of the country had their graduation.^[19]

Professional Education

Venezuelan librarianship professional formation was in part caused and inspired by the seminal speech that José Ortega y Gasset delivered in the Second IFLA International Congress, in the Universidad de Madrid, on May 20, 1935. The mentioned discourse was published as the book titled *Librarian's Mission*, which was the way these ideas were disseminated in Venezuela, before there were professional education schools. The mentioned ideas made people start to realize that the profession was a collective need and it was socially indispensable, thus making vital to professionalize a traditionally empirical occupation.^[20] Some of Ortega y Gasset's ideas that are inherent to the essence of Venezuelan information professionals and the early curriculum designs are 1) a concern with enabling access to information as a human right, either for the purpose of scientific and financial advancement as well as for communication and recreation; and 2) the idea that the right to information is the means that ensures the scientific, humanistic, technological, and social progress of the country and the world.^[20]

Moreover, from the cited ideas, library, and archives, schools are responsible of developing professionals who may contribute in part to their profession, through teaching and research; and also to society, being aware of social, financial, and scientific development at a global level and to answer any need of information, science, and culture that society may have. The national professional training has seven bases that were stated from the beginning as different skills: basic, administrative, technical processing, information sources, documentation and information, research, and understanding of human nature.^[20] These bases have been kept until today, adding additional facets such as to have historical and social consciousness of the objects and areas of study, as well as topics of social relevance such as user formation, reading promotion programs, and information literacy. Moreover, there are the technological facets, of information policies, and of informetrics. All these facets are not necessarily integrated in the compulsory curriculum, but they may be developed by the student through elective courses or as transversal axes in the curriculum design. Regarding their attitudes, the ideal professional must be competent, critical, reflexive, and participant in the issues of their context. Additionally, good Venezuelan librarians are characterized for their service vocation, constancy, professionalism, their lifelong learning, and for pushing to the limit the resources and possibilities at their disposal for providing their services and fulfilling their mission.

It is complicated to summarize the current state, the challenges, and opportunities of Venezuelan professional training, because every institution has their characteristics

and circumstances. In the frame of developing some contributions to the curricular change, three stages of the curricular evolution in the EBA-UCV have been defined: technical, disciplinary, and transdisciplinary, indicating that the revision and updating of the curriculum and the naming of the professional studies in the field have been deferred.^[21] The transition in the EBA-LUZ has passed from a theoretical and technical formation, then reinforcing management and technological areas, and finally it has diminished the general formation, enhancing professional and research courses.^[21,22] In both cases, the main considerations behind the initiatives of curricular change have been driven by academic and employment dynamics, both nationally and internationally, which are also what informs the construction of the professional profile. In the country, there have been curricular evaluations in the EBA-LUZ^[22] as well as comparative evaluations between the Venezuelan curricula. The latter have set the bases for developing guidelines and methodologies to guarantee aspects such as quality assurance, pertinence of formation, the degree to which formation answers the needs of the discipline and society, the possibility of national and international accreditation, and internationalization.^[23] Regarding the comparative study of Venezuelan curricula, it turns out that both are academicist, humanistic, and sociological, but the elements to revise in national curriculum design are teleological, axiological, transdisciplinary, cooperation, and interchange fundamentals, as well as to develop market studies to achieve an empirical and common grounding for curricula design, being aware of the local and global relationship, to strengthen the construction of a pedagogical theory, and encourage the configuration of knowledge, learning, and research networks.^[24] Finally, the need of introducing the competency-based curriculum has been stressed, and it is something that the EBA-LUZ has already tried.^[25]

Apart from the cited experiences that improve the curricula, some authors highlight the dubious need of framing the curriculum to the initiatives of the current Venezuelan government administration (1999–2014), thus presenting the Information Sciences Formation Program.^[26] This program, given its definition and except for its ideological fixation, results redundant when considering the already established learning options, as it indicates that it is innovative simply because it seeks to overcome anachronisms that sadly are grounded in the general perception that people have about the information professional but that the mentioned traditional university formation already takes into account. These perceptions are the exclusive role of a custodian, to grant access to information to the communities, and to improve means and devices for information handling. In conclusion, this tends to erroneously insinuate that the established formation programs do not take into account the needs of the society as well as those from public and private institutions.

CURRENT STATE

The Venezuelan situation has become more complicated during the last 22 years, with events that have resulted in the current and never before seen financial, political, and social crisis, such as the Black Friday, the Caracazo, failed coups d'état, trials to government officers for corruption charges, a new Constitution, devaluations and currency exchange controls, a new political class in power, the enterprise and oil strikes, instability, an unsafe country, as well as polarization and confrontation. It is only to be expected that Venezuelan libraries and librarianship are outside of these issues and like it has happened with other sectors, they have suffered the ideological and polarizing onslaughts that have been occurring during current government administration (1999–2014).

Libraries and Their Public

For 1999, Venezuela had already shown a high literacy rate, with approximately 92.3% of the population of over 15 years.^[27] However, it seems that in Venezuela, the discussions on libraries have been put aside, because of the country's situation, of society, and librarians themselves, of the development of information and communication technologies (ICTs) or because the Internet has displaced reference librarians and now everyone searches independently for information, for better or worse. Moreover, libraries have not been given their place, importance, and the fundamental value they deserve, thus there is a general lack of interest in them. The figures confirm it, 80% of the population recognizes that they do not go to a library, barely a 9.1% visits a public library, and an ephemeral 1.2% goes to the NL for information and education needs.^[28] Officially, it has been reported as a significant achievement that in 2012, the NL had attended more than 11 million users (p. 414).^[29] Furthermore, the paradox of a raising number of readers but not of books sold is starting to be envisaged. The main cause of this phenomenon can be found in the infamous currency exchange control, which is described in the following section.

Financial Issues

In order to discuss the financial issues of Venezuela, it is necessary to take into account the presence of a set of complex rules that have regulated a governmental currency exchange control during the past 12 years. These rules have contributed to a massive inflation, costs speculation, and innumerable challenges for any person or institution intending to travel or acquire imported products or services. This currency control was established in 2003, it is based on official exchange rates for US Dollars (USD) and Euros, and it is still in place with complementary or

alternative currency exchange systems. These schemes complicate the financial situation, because they started with an exchange rate of 1.60 Bolívars Fuertes (BsF) for each USD, then BsF 1.92/USD in 2004, and BsF 6.30/USD in 2013.

Today, the currency control is based on a new scheme of three values, one fixed to 6.30/USD for “priority” sectors and the other two are “complementary”: the first starts at BsF 11.36/USD, but with high fluctuations, and the second is an alternative system that seeks to eliminate the alternative black market, by fluctuating according to supply and demand, and starting at BsF 51.86/USD. This control, together with the currency reconversion of 2008, which eliminated 3 zeroes to the national currency and the calculation of the National Budget according to the prices of the oil barrel, has resulted in the creation of development funds that are discretionally managed by the government and has cast serious doubts about their transparency. Academic libraries have felt the most direct impact of the currency exchange control, because for them it is very hard, if not impossible, to receive the foreign currency needed to subscribe academic databases and import library materials that are not manufactured in the country. This makes the IVIC library, because of its subordination to the State, one of the few libraries of the country that can currently count with these resources.

The current main economic activity of the country is the oil exploitation, between 2000 and 2008 there was a spectacular rise in oil barrel prices, from 20 to more than a 100 USD. Despite its condition of being a single product economy, Venezuela has been privileged because of the volatility of prices and the immediate liquidity of oil sales in the international market. According to the National Institute of Statistics, between 2003 and 2012, the government made a social inversion (SI) of 772,000 million USD, mainly through the so-called Social Missions. The SI for the period 1999–2011 represented around 60% of the State’s income.^[30] Moreover, between 2008 and 2012, the State oil company *Petróleos de Venezuela* (PDVSA) received a total income of 520,000 million USD (p. 156).^[31] It has been calculated that the revenue for 2013 was between 82,000 and 85,000 million USD.^[32]

Between 2004 and 2009, Venezuelan SI was directed firstly toward education, then social security, health, housing and services, social development, and participation.^[33] However, the investments made in culture, communication, and science and technology occupy a precarious space in the assignment of public expenditures. Considering the magnitude of the SI, it is valid to ask how much have been invested in Venezuelan libraries. Sadly, it is difficult to offer a detailed scenario with the scarce statistical data offered by the NLAILS; moreover, on its website there are no data available on any library indicator. Furthermore, the available statistics go only as far as 2005, and except for the *Cultural Statistical Yearbook, 1990–2003: Venezuelan Book’s and Libraries’ numbers*;^[15]

one copy of the *2007 Statistical Yearbook of the NL* and the *Annual Reports and Accounts of the Ministry of Culture* (MCMPPC),^[34] there are not enough pertinent data sources. Through the study of the different editions of this last source, it is possible to calculate that the total inversion dedicated to the NLAILS and hence to our libraries between 2005 and 2013 was of 1169.9 million BsF, or 315.9 million USD. During this period, NLAILS has directed its plans through projects which essentially reiterate every year the reinforcement and push of the NLAILS and the NSPL. This indicates that this goal has not being achieved or not completed. It also means that the majority of the resources should have been directed to invest and develop the NSPL.^[34] In order to put the previously mentioned amount in perspective, we can take into account that PDVSA’s income between 2008 and 2012 was over 520,000 million USD. Then, the resources transferred to the NLAILS in the same period were of 186.4 million USD. This means that the SI directed to the PL sector in Venezuela represents 0.03% of the total revenue generated by the sales of oil. Thus, a great deal of the issues of the NSPL is originated by budget problems.

The obstacles highlighted in NLAILS report during the execution of the mentioned projects are insufficiency of financial resources, insufficient assignation provided by the *Law of Budget*, suspension of the Information System *Northwestern Online Total Integrated System* (NOTIS), noncompliance of the *Law of Legal Deposit*, cuts in the planned investments for the acquisition of collections, deterioration of infrastructures, lack of preventive and corrective maintenance of the public libraries, obsolescence of computer equipment, obsolescence of collections, lack of resources for the paper edition and dissemination of technical documents for librarians, difficulties for compiling statistics, lack of imported resources and materials which affect the activities of preservation and conservation, lack of capable and specialized professionals, among others.^[15,34] Moreover, the lines of action of recent projects start to contain an ideological charge, by talking of concepts such as the *First Socialist Plan*.

Most of the challenges academic libraries and the NLAILS are reporting and facing are related to financial issues, which are aggravated by the currency control. The main problem for libraries is that very few of the resources they must acquire are currently manufactured or sold within the country. Hence, the resources that can be imported imply extra charges over the product’s cost, which are derived from the currency control itself, the speculation of costs, and disproportionate import duties and taxes from the State. This situation is further complicated for public libraries, from the NLAILS to the smallest ones, because budget allocations are marginal. The currency control and the scarce financial resources are part of a vicious circle, because with the limited budgets libraries can acquire less resources every year due to the fluctuation of exchange rates, together with inflation, speculation, and State taxes that do not forgive even books.

Legal Issues

NLAIS' administrative activities face different lingering challenges; the majority of them are caused by budget insufficiency, which raises some doubts about the legal bases supporting our libraries, the convenience of institutionalism, centralization, decentralization, or administrative de-concentration. Libraries' public service character is mandated by the Constitution of the Bolivarian Republic of Venezuela (CBRV),^[35] but the question is: how we can socially transform libraries in order to fulfill this constitutional mandate that would be their *raison d'être*? Article 108 is the only part of the CBRV where the word "library" appears, it states:

"Media, both public and private, must contribute to citizen formation. The State will guarantee public services of radio, television, and library and computer networks, with the purpose of allowing universal access to information. Educational centers must incorporate the knowledge and application of new technologies, their innovations, according to the requirements established by law" (p. 23).^[35]

Apart from the first and only *NLAIS Law*,^[8] other two legal instruments have supported libraries: 1) *Legal Deposit Law* of 1993, which compels the editorial sector to send a copy of all publications produced in the country to the NL; and 2) *Organic Municipal Regime Law* of 1989, which mandated the existence of municipal PL according to the amount of inhabitants or population, but such disposition is nowhere to be found in the new *Organic Public Municipal Power Law* of 2010, which replaced the previously mentioned legislation. CERLALC points out that Venezuela does not offer data regarding reading and library indicators (p. 5),^[36] specifically the number of PL for every 100,000 inhabitants. This is due in part to the elimination from the current legislation of the requirement of offering municipal library services. However, recently the NLAIS Press Department declared that a new NL Law is being drafted, announcing the "discussion" of a project. It draws attention to the fact that this notice seems to be a reaction in front of the controversial *Organic Culture Law*, approved in August 2013 and also that the promoters of the so-called library constituent are conducting the "debate and analysis" of the future legal text behind closed doors, when what would be required is a broad, open, diverse, and inclusive consultation, which is characteristic of the participative democracy advocated by the CBRV.^[35] This consultation should count not only with working groups in the NL, but it should also take into account what the traditional library schools might have to say, as well as the professional associations (despite their dispersion), the national library workers, cultural promoters, and citizens.

CONCLUSION

This is the moment to vindicate Venezuelan libraries, to restore their fundamental value, and teach their usefulness

to the nation's development. Information professionals and librarians have the responsibility of demonstrating the vital importance of libraries to political leaders, and to make sure their constitutional provision is assumed on the basis of human rights. National library schools must include in their curricular design a much broader and less rigid social vision of libraries, which allow for the identification of the professional role in front of society and diverse communities. Research and comparative librarianship are essential to entrepreneurship, innovation, and competitiveness in a world that is increasingly an information society.

Venezuela faces one of the most difficult times of its history. Libraries as institutions and librarianship as profession are instruments for social change and the strengthening of democracy. It is fundamental, now more than ever, to make Venezuelans understand that without information, education, and culture there would never be a "powerful country," much less a "motherland." Before extracting all oil reserves, we must learn to read, and to think in a free, critical, and selective way. Moreover, we have to see our fellowmen as just one more person in the construction of great deeds and not as an adversary that must be ignored because of their political affiliation or their ideology. Finally, before building bridges, highways, schools, hospitals, or even large libraries, first we must build citizenship together. Being citizens is what will open us the way toward development.

Version Control

Jill E. Grogg

Libraries, University of Alabama, Tuscaloosa, Alabama, U.S.A.

Jeff Weddle

School of Library and Information Studies, University of Alabama, Tuscaloosa, Alabama, U.S.A.

Abstract

Broadly, version control is the attempt to define the relationships among multiple iterations of a scholarly text, particularly journal articles. Version control existed in the print world, but the electronic environment has exacerbated the matter due to a number of varied factors, including the ease with which digital scholarship can be distributed and adapted. Political and technological issues also affect the problem of version control. Because any given article may have a preprint, a postprint, a version in the official journal, and a version in an institutional repository, among other copies, some mechanism must exist to relate and explain the relationships among these manifestations. Several current initiatives are underway within the information industry to address the problem of version control.

INTRODUCTION

For library and information science, version control is the activity of identifying and managing iterations of a document for archival and retrieval purposes. While version control can be problematic for documents and information objects of all types and formats, it is especially so for scholarly communication—particularly journal articles—distributed in electronic formats.

In all the many unforeseen challenges that electronic publishing has unleashed for the information profession, there exist two principle elements: political and technical. Version control is no exception. Many stakeholders in the information industry are shaping the version control discussion, and these discussions have resulted in recommended solutions and directions.

In 2002, a research team headed by Raymond Siemens produced a report entitled “The Credibility of Electronic Publishing” for the Humanities and Social Sciences Federation of Canada (HSSFC). This report attempted to define and assess the current state of affairs for scholarly electronic publishing as well as provide some recommendations for future action.^[1] One of the sections of the report, “Archiving and Text Fluidity/Version Control,” specifically addresses the unique situation that electronic publishing presents for text alteration. In this section, members of the HSSFC-appointed research team note:

Texts can be adapted, abstracted, translated, edited, condensed, corrected, marked up, transcribed, annotated, amended, paraphrased, transliterated, illustrated, indexed, or abridged. They can be commented upon or referenced by other texts. They can be analysed or synthesized.

These modifications, and any others that might be considered, produce distinct versions, all related to the original text.^[2]

Indeed, what is important to note is that any alteration(s) to an original text produces a distinct version. Therefore, versions of a text need to be uniquely identifiable while simultaneously containing information that describes the relationships among the various versions. Version control, then, is the effort to “name the versions of the text” and to specify “the differences between the revision and the original text.”^[2] Moreover, version control endeavors to define what is meant by the original and authoritative text.

In 2005, the U.S. Government Printing Office (GPO) prepared a white paper on version control of documents within the purview of the Federal Depository Library Program. The GPO was particularly concerned with electronically disseminated documents. Government Printing Office concerns fall into seven broad categories. These include version definition, or “unique manifestation of a publication”; version control, which includes “acquiring, cataloging, storing, preserving, and retrieving different versions of publications”; version triggers, which are changes that exceed agreed upon limits; version detection, which deals with identifying and detecting alternate versions; version identifiers, which are metadata tags; version crosswalks, which are a subset of version identifiers and provide links to all other versions; and depository library responsibilities for superseded versions. While it focuses on government documents, the GPO report is extensible in that it offers parameters that can be applied to any discussion of version control.^[3]

In April 2008, the National Information Standards Organization (NISO), in partnership with the Association of Learned and Professional Society Publishers (ALPSP), released a report that defines specific stages or iterations of a journal article. Similar to the GPO's seven broad categories, the NISO/ALPSP Journal Article Versions (JAV) Technical Working Group identified seven terms, or stages, of an article's development. According to members of the JAV Technical Working Group, the report is meant to offer recommended practices for the scholarly publishing community. The report summarizes the issue:

Researchers, their institutions, and journal publishers are rapidly moving on from using static, single copies of research papers that are essentially "images" of a printed document. Changes in the way we create, edit, circulate, validate, publish, find, use, and update articles are producing multiple versions whose status and provenance is often unclear. Online searching now allows multiple versions to be found but rarely makes clear the relationships between them.^[4]

Specific recommendations of the group are discussed in subsequent sections.

SCOPE AND HISTORY

Standards, rules, local practices, terminology, and definitions evolved over many years to ensure version control of printed matter. Even so, it has always been problematic to ensure that a published text is in complete agreement with all other versions of that text. Pirated or plagiarized editions, misreadings of manuscripts, and other issues have long clouded issues of text authenticity and authority. With the emergence of electronic publications, these rules, practices, and so forth face much greater challenges. Contemporary efforts to address long-standing problems of unique manuscript identification are addressed by Matthew J. Driscoll in "The MASTER Project: Defining Standards for Electronic Manuscript Catalog Records." The international Manuscript Access through Standards for Electronic Records (MASTER) Project's "document type definition" (DTD) standards and application of the closely associated Text Encoding Initiative's (TEI) *Guidelines for Electronic Text Encoding and Interchange* are applied to archived medieval manuscripts. TEI guidelines allow for description along several broad and flexible categories, including its physical location; title, place of origin, and language(s); contents; physical description; history; and administrative issues such as availability and custodial history.^[5]

The shift from printed manuscripts to electronic documents greatly accelerated the appearance of document iteration. This acceleration becomes problematic when coupled with the fact that gate-keeping functions

traditionally associated with scholarly and commercial publishing diminish when authors, or any other person, can, in some cases, disregard copyright law and change a text at will, store it on a server, and disseminate it via whatever scheme he or she chooses. Copyright becomes a tangled Web when one considers that the author may no longer hold copyright to his or her own work if he or she has agreed to transfer copyright to the publisher for a limited or unlimited amount of time. Therefore, he or she may not possess the legal permission to post particular versions—especially the final "published" version—of his or her own work by self-archiving on a personal Web site or in an institutional repository.

Self-archiving is usually the process of an author maintaining a document copy in electronic format. This electronic document may be made available to the author or anyone else designated by the author. The clear benefit of self-archiving is easy access and information dissemination within the scholarly community. One potentially negative consequence is that variant versions of a particular document may circulate in this way. An institutional repository is "defined to be a Web-based database (repository) of scholarly material which is institutionally defined (as opposed to a subject-based repository)"^[6]

Issues of copyright and permission to disseminate work are usually negotiated between the author and the publisher at the time of publication; many publishers have specific policies and guidelines regarding how an author may alter and/or disseminate versions of his or her work after publication. For instance, some publishers allow authors to retain copyright to their work but negotiate from the author the one-time rights, exclusive for a given amount of time (e.g., 90 days), to be the first publisher of the work, and the right to distribute the work exclusively for a given amount of time (e.g., 90 days) after publication. After this predetermined period (e.g., 90 days), the author may distribute, reprint, etc., as he or she pleases. On the other end of the spectrum, some publishers have much stricter and more limited agreements with authors wherein the author transfers copyright to the publisher in perpetuity.

Regardless of the copyright issues involved and the myriad possibilities for agreements between the publisher and the author, it remains that many different versions of any given article do and can exist. To focus on the journal article for purposes of explication, one journal article can exist in multiple electronic versions. In 2005, Sally Morris offered a partial list of possible versions of one journal article:

1. Privately circulated early draft (could be >1 iteration).
2. Version presented at public event (again, could be >1).
3. Pre-submission version(s).
4. Version as submitted to journal x (may differ when resubmitted to journal y).
5. Version amended after peer review (may go through >1 round of amendment).

6. Version as accepted by journal x.
7. Accepted version, with substantive editing by journal editor and/or publisher (again, may be multiple iterations).
8. Accepted version, with substantive editing and copyediting—ready for publication.
9. Publication version (as above, formatted and paginated)—proof.
10. Publication version corrected and passed for publication.
11. Published version, not on publisher's site (e.g., PDF), thus potentially lacking some functionality.
12. Published version (on publisher's site, with full functionality).
13. Post-publication version with errata/addenda (maybe on publisher's site, with functionality) or elsewhere without it.^[7]

VERSION OF RECORD AND OPEN ACCESS

While it is beyond the scope of this entry to explore the complicated world of open access (OA), it is impossible to discuss version control without addressing some of the major features of OA. Broadly, OA is the movement to make scholarly literature “digital, online, free of charge, and free of most copyright and licensing restrictions.”^[8] Morris does not explicitly refer to any particular publishing models in her list; she does not overtly refer to OA or toll-based models because version control issues prevail in both worlds. Indeed, journal articles published in the more traditional toll-based scholarly literature, or journal articles published in OA journals can be versions of record.

The NISO/ALPSP JAV Technical Working Group defines version of record (VoR): “a fixed version of a journal article that has been made available by any organization that acts as a publisher by formally and exclusively declaring the article ‘published.’”^[4] Furthermore, the notes to the VoR definition explain:

The VoR may exist in more than one location (e.g., a publisher's Web site, an aggregator site, and one or more repositories). That is, there may be more than one *copy* of a VoR but there is only one *version* of a VoR. In Functional Requirements for Bibliographic Records (FRBR) terms, there may be more than one *manifestation* or *instance* of a VoR, but there is only one *expression* of it.^[4]

In other words, VoR transcends notions of multiple copies. Yet, the increasing prevalence OA archives and repositories have ultimately complicated the issue of version control for the scholarly community. The mere existence of such OA material (and other toll-based copies such as those that exist in aggregator databases) requires the reliance on FRBR differentiation between manifestation and expression.

Version control faces two distinct sets of challenges: political and technological. OA itself is an increasingly

political movement, especially in light of the Consolidated Appropriations Act, 2008, which includes a provision directing the National Institutes of Health (NIH) to require “scientists to submit final peer-reviewed journal manuscripts that arise from NIH funds to the digital archive PubMed Central upon acceptance for publication.”^[9] This Act was signed into law despite lobbying efforts of the Partnership for Research Integrity in Science and Medicine (<http://www.prismcoalition.org>), which is a coalition that has the support of the Professional and Scholarly Publishing Division of the Association of American Publishing.

In addition to the complexities that OA introduces, version control often resembles a Gordian knot because divergent groups have a vested interest in insuring that their voices are heard in any effort to create standardized solutions. Publishers, authors, researchers, vendors, aggregators, subscription agents, OA advocates, universities and other research centers, librarians, standards organizations—while there is some consensus of opinion among this variegated list, each group nonetheless represents a particular constituency with unique goals and interests. The JAV Technical Working Group's report lists the following stakeholders as important variables in identifying the dimensions of an article version: author, editor, referee, publisher, librarian, reader, and funder. Other dimensions articulated by the JAV Technical Working Group are time, added value, manifestation, and siblings.^[4]

PEER REVIEW

In 2000, a working group of publishers acknowledged one outcome of the version control problem as changing the context within which peer-reviewed articles are perceived: “The peer-reviewed article will continue to play a crucial part in the certification, communication, and recording of scientific research. However, in the electronic environment it represents one point on a potential continuum of communication.”^[10] Peer review—in one form or another—has represented the bedrock of reputable scholarly output since at least the beginning of modern science in the seventeenth century, and any discussion of a potential change in its role in scholarly communication is significant.

The issue of peer review as it relates to OA and thus version control is a volatile one, with information industry stakeholders arguing many sides of this complicated issue. Some say that peer review in OA scholarly output is as rigorous and honest as it is within conventional toll-based publishing; others argue that peer review and thus quality of scholarship suffers in the face of OA. In her 2005 article, “Version Control of Journal Articles,” Morris noted the emerging problem of definitive or authoritative versions of documents versus “good enough” versions and its implications for scholars. The problem, as described by Morris, is pernicious. As listed earlier, she identifies 13

basic variants, from privately circulated early drafts, through post-publication versions with errata and addenda and argues that a reader cannot easily discern differences between these versions.^[11]

Steven Harnad addresses the worries of researchers, university administrators, and librarians in terms of version control and peer review. He notes that there is no need to be concerned about self-archiving because:

There will be self-archived preprints, revised drafts, final accepted, published drafts (postprints), updated, corrected post-postprints, peer comments, author replies, revised second editions. OAI-compliant Eprint Archives will tag each version with a unique identifier. All versions will be retrieved by a cross-archive OAI search, and the 'hits' can then be identified and compared by the user to select the most recent, official or definitive draft, exactly as if they had all been found in the same index catalog.^[12]

OAI is the Open Archives Initiative, and it “develops and promotes interoperability standards that aim to facilitate the efficient dissemination of content.”^[13]

APPROPRIATE COPY AND OpenURL

In addition to the implications for readers, Morris observed that version control is of great concern to libraries, which are faced with the multifaceted problems of tight budgets; appropriate copies based upon institutional affiliation; multiple, free online versions; and versions which are either self-archived or archived by independent institutions or other repositories. In response to some of these issues, libraries point users to their appropriate copy via link resolvers and the OpenURL framework. It is important to distinguish between the version control and the appropriate copy problem. The appropriate copy problem has two equal dimensions: 1) the multiple availability of any given resource from a variety of sources and 2) the subsequent challenge of pointing the reader to the copy of this resource appropriate for him or her, usually by virtue of his or her institutional affiliations.

If restricted to the toll-based universe, a given journal article might be available from the publisher or from a number of secondary aggregators (e.g., EBSCO, ProQuest, Gale). A researcher at a university may have access to only some of these article copies, and the library or information center wants to insure that the researcher reaches those copies which are appropriate for him or her. If expanded to include the OA universe of materials, the phrase “appropriate copy” then comes to “denote the copy of a resource to which a user has rightful access, usually by virtue of his or her institutional affiliations but perhaps also by virtue of an information object being *open access*.”^[14]

The OpenURL framework was developed to address the appropriate copy problem, and it is now a NISO

standard, Z39.88, OpenURL v. 1.0. Via link resolvers, the OpenURL framework is widely used to point users to their appropriate copies. The appropriate copy problem and its solution in OpenURL/link resolvers primarily address a problem of access; version control, on the other hand encompasses issues of authority and management as well as defining the stages in the life cycle of an article. OpenURL also primarily focuses on pointing users to versions of record, which, again, can be in multiple locations. The other versions of an article—such as more ephemeral ones kept in an author’s institutional repository, for example—are currently outside the technical capability of the OpenURL/link resolvers. With version control, many technological hurdles remain, including: a standardized schema to identify the VoR or authoritative version as well as an extensible model to identify and explain the relationships among the different iterations of a document.

TECHNOLOGICAL INITIATIVES

One such effort to clearly articulate the different stages in the life of an article as well as the relationships among those stages was released in an April 2008 report by a joint partnership between NISO and ALPSP, the JAV Technical Working Group. Perhaps the most definitive work to date on the issue of version control, the recommended practices released by the JAV Technical Working Group attempts to “provide a simple, practical way of describing the versions of scholarly journal articles that typically appear online before, during and after formal journal publication.”^[4] The working group builds upon earlier, previously mentioned efforts.

In September 2005, NISO and ALPSP charged the group with creating a plan that included:

1. Creation of use cases to identify the most common journal article life cycles.
2. Analysis of use cases to determine common life cycle stages.
3. Selection of preferred vocabulary for the most common life cycle stages.
4. Development of appropriate metadata to identify each variant version and its relationship to other versions, in particular the definitive, fully functional published version.
5. Establishment of practical systems for ensuring that the metadata is applied by authors or repository managers and publishers.^[15]

Cliff Morgan, Vice President, Planning and Development and Director, John Wiley & Sons, Ltd., was the chair of the joint NISO/ALPSP working group. In an August 2007 interview, Morgan noted: “In the digital world, multiple versions of journal articles are often available online. This can cause confusion because there is no way of identifying

the various versions by either a common terminology or identification scheme.” Morgan went on to explain that the working group “will recommend terms and definitions for journal article versions and define the relationships between these versions. We’re focusing on key stages rather than every possible iteration of an article from origination to publication.”^[16]

Critical to the working group’s efforts is the notion that the group focuses on “key stages” of the version continuum rather than “every possible iteration.” The group considered a variety of attributes in order to describe different versions: “Ownership, bibliographic context, identifiers [e.g., digital object identifier (DOI)], relationships, fixity, and peer review are explicitly stated in the terms and definitions that we recommend. They can be described by the article version names and some are already covered by standard metadata elements (e.g., bibliographic reference, date, and DOI).”^[4] Of particular note is the attention paid to the version of record. Morgan elucidated the importance of this stage:

The VoR constitutes the ‘minutes of science’—the formally certified record of a research project. It is this version that has been peer-reviewed, edited, composed, and verified by the author; it is this version that benefits from publisher investment in managing the above process, building the journal brand, and adding functionality such as linking and e-alerts, and for which the publisher takes legal responsibility. This is also the version that is most likely to be cited by other researchers.^[16]

If the VoR is easily identifiable, then the problem of researchers questioning which version is the final, authoritative one is solved.

The seven stages identified by the working group are:

1. Author’s Original.
2. Submitted Manuscript Under Review.
3. Accepted Manuscript.
4. Proof.
5. Version of Record.
6. Corrected Version of Record.
7. Enhanced Version of Record.

Each stage is accompanied by a full definition and note. Also included in the report are graphical representations of the relationships among formal and gray literature as well as a number of “use cases” to provide a clearer picture of how the recommended terms would apply in real-world situations.

What remains to be seen is to what extent the recommendations in the report will be implemented by publishers and other stakeholders in the information industry. Version control is still very much an issue in flux, and thus it presents interested parties with a moving target. Some publishers have already created and maintained internal

practices for version control that may or may not be consistent with the group’s recommended practices. If a publisher has invested significant capital in creating and maintaining an internal schema, then only time will tell if the said publisher will implement the NISO/ALPSP recommendations. Additionally, while the report explains some relationships among formal and gray literature, the group primarily concerned itself with a fairly narrow scope: journal articles. The continued evolution of the formally published journal article itself presents problems. If the electronic version with an assigned DOI is the version of record, then it begs the question about the necessity of assigning volume, issue, and page numbers for a journal article version of record. Questions of version control for other formal literature—book chapters, proceedings, etc.—remain. Moreover, an ocean of gray literature exists. With the advent of electronic publishing, gray literature and other informal publishing enjoy unprecedented accessibility. Such accessibility arguably leads to formerly “hidden” scholarship now occupying a more prominent place in our intellectual space and community of scholarship. Ultimately, many questions remain and while the group’s work is essential, it is only one step toward an unknown future.

Version control is an international issue and as such, there are multiple initiatives underway to address its unique challenges. Two other programs created to study version control are the United Kingdom-based Joint Information Systems Committee Validating Repository Content project (VALREC, http://www.jisc.ac.uk/whatwedo/programmes/programme_rep_pres/tools/valrec.aspx and <http://valrec.eprints.org/>) and the London School of Economics VERSIONS Project (<http://www.lse.ac.uk/library/versions/>).

CONCLUSION

Version control remains a thorny issue with many technological and political barriers. The very nature of electronic information allows for an ease of replication and adaptation heretofore unheard of in scholarly communication. However, information industry stakeholders have recognized the issue and have formed a variety of international projects to study and recommend standardized solutions for identifying and managing iterations of a document for archival and retrieval purposes.

Vietnam: Libraries, Archives, and Museums

Robert D. Stueart

Graduate School of Library and Information Science, Simmons College, Boston, Massachusetts, U.S.A.

Abstract

Vietnam has a long and illustrious history of information services development - from the introduction of printing in the 14th Century, through the French influence in the 19th Century when many valuable collections and guidelines for libraries were developed, to the modern advances information services development, with some state-of-the-art information centers and services. The richness of the culture and the development of the society is reflected in the valuable collections and services currently offered in it's libraries, information centers, museums and archives.

SOCIALIST REPUBLIC OF VIETNAM (CONG HOA XA HOI CHU NGHIA VIETNAM)

VIETNAM

Vietnam, a 1500 km narrow stretch of land, is located in Southeast Asia, bordered by the Gulf of Tonkin and the South China Sea to the east, China to the north, Laos and Cambodia to the west, and the Gulf of Thailand to the south (see Fig. 1). Diacritical Vietnamese language marks have not been used in this entry, to simplify printing.

History

The modern-day history of Vietnam dates back to the tenth century—during the time that the Ngo (939–965), Dinh (968–80), and Pre-Le (980–1009) dynasties began to consolidate and defend an independent country. Previous to that Vietnam had been conquered by China in 207 B.C. and dominated by Han until the 111 B.C. In the fifteenth century, China made its final attempt to dominate Vietnam but was defeated.

Commencing in the mid-nineteenth century, the country came under the dominance of France when Indochina, consisting of Vietnam, Cambodia, and Laos, was established under a French decree of 1857. Vietnam declared independence from Japan and France on September 2, 1945. However, it remained under French control until the communist Viet Minh defeated French forces at Dien Bien Phu on May 5, 1954.

The Vietnamese trace the origins of their culture and nation to the fertile plains of the Red River Delta in northern Vietnam. After centuries of developing a civilization and economy based on the cultivation of irrigated rice, the Vietnamese, in the tenth century, began expanding southward in search of new rice lands. Until the mid-nineteenth century, the Vietnamese gradually moved down the

narrow coastal plain of the Indochina Peninsula, ultimately extending their reach into the broad Mekong River Delta.

The conquest of Vietnam by France began in 1858 and was completed by 1884. It became part of French Indochina in 1887. Vietnam declared independence after World War II, but France continued to rule until its 1954 defeat by Communist forces under Ho Chi Minh. Under the Geneva Accords of 1954, Vietnam was temporarily divided at the 17th parallel when North Vietnam was reconstructed as the Democratic Republic of Vietnam. South Vietnam struggled another 20 years for independence against U.S. forces and Saigon's government until the Paris Agreements of 1973 when U.S. troops withdrew. In 1975, Ho Chi Minh and his forces overthrew the Saigon Government and unified the country as the Socialist Republic of Vietnam, with Hanoi being declared the capitol. As of 2005, a three-person collective leadership has been responsible for governing Vietnam. This triumvirate consists of the Vietnam Communist Party, VCP General Secretary, the Prime Minister and the President.

Vietnam's history is a story of struggle to develop a sense of nationhood and to maintain that against internal and external pressures.

Population

Vietnam's population is over 84 million, and is growing at a rate of about 1.2% each year.^[1] Recent estimates put Vietnam's age distribution as follows: 0–14 years of age, 29.4%; 15–64, 65%; and 65 and older, 5.6%.

Vietnamese, or "Viets," also known as Kinh, are the predominant ethnic group, constituting about 86% of the population. Chinese account for 3% of the population, while the remaining numbers are of other ethnic backgrounds—estimated at around 54 groups—the largest being the Hmong, Thai, Khmer, Cham, and Montagnards.

Fig. 1 Map of Vietnam.

Source: CIA *The World Factbook*.

Most of these indigenous live in the Central Highlands and extreme northern Vietnam.

Vietnamese is the official language of Vietnam, with English increasing in popularity as a second language. French remains a language of record for many historical documents, and some Russian documents are of note. With 7.6 million followers, Buddhism is the most popular religion. The second most popular religion is Roman Catholicism, with 6 million adherents.

Vietnam's literacy rate is about 94%, including 95.8% for men and 92.3% for women. Educational attainment is less impressive. Although, 5 years of primary school education is compulsory, and about 92% of eligible children are enrolled in primary school, only about two-thirds of them complete the fifth grade.

Economy

Although Vietnam's economy, which continues to expand at an annual rate in excess of 7%, is one of the fastest growing in the world, that economy is growing from a low base. It still reflects the crippling effect of the Second Indochina War (1954–1975) and the repressive economic measures introduced in its aftermath.^[2]

LIBRARIES

Libraries and information centers in Vietnam can be categorized in two groups: 1) a network of scientific libraries (National System of Scientific and Technological Information—NSSTI) and 2) a network of public libraries, including central, city and provincial, district and children's libraries.

History

The introduction of printing, using wooden blocks and boards, has been dated sometime after the fourteenth century. However, manuscripts, dating before that time, formed the first collections of “library” materials. Much of the collections developed before the time of the Nguyen dynasties in Hue (1802–1945) have been lost or destroyed due to civil wars and invasions and only about a fourth of the Nguyen collections survived the wars of the twentieth century.^[3] Many of those surviving Han-Nom writings (combining the classical Chinese characters of Han with Nom, the Vietnamese language style) are now located in the Vietnam Academy of Social Sciences—Institute of Han-Nom Studies in Hanoi which has a large number of ancient texts on Confucianism in VietNam.^[4] During the second part of the nineteenth century, French colonization of Vietnam brought the development of a number of libraries, including libraries of the Société des Etudes Indochinoises and the École Française d'Extrême Orient (EFEO). Most of those early collections belonged to learned societies or the government under French direction.

In 1917 a Frenchman, Paul Bourdet, arrived in Vietnam and immediately introduced the idea of development of a Direction des Archives et des Bibliothèques de l'Indochine^[5] in order to:

- Establish a central library and archive in Hanoi, with branches in Saigon, Hue, and Hai Phong (this latter one

never materialized), as well as Phnom Penh in Cambodia and Vientiane in Laos

- Develop and institute legal deposit laws
- Initiate cooperative assistance to other libraries and archives in existence^[6]

The library in Saigon became the Bibliothèque Central Cochinchine and adopted the role of that earlier Library and Archives (BCC). In 1919, the Bibliothèque Centrale Hanoi (BCH) was created with legal depository rights for all of Indochina.

In the first half of the twentieth century, several major collections were developed in libraries, particularly in Hanoi and Saigon. However, in 1945, with the commencement of military conflicts with Japan many resources were damaged and some were moved to France in the early 1950s. With internal conflict came a move to relocate some resources, including books, journals and archives, from the Bibliothèque Central Hanoi (BCH) in Hanoi to Saigon. In 1959, the Directorate of National Archives and Libraries (DNAL) was established in South Vietnam with the aim of creating a national library with resources from the old BCC and those materials brought south, while some were removed to France. The resources of this new unit became what was called the General Library [now the General Science Library, the major public library—other than the National Library of Vietnam (NLV)] which was named the National Library of South Vietnam in 1971 when a new library building was opened. Three years later the DNAL was disbanded. The library holdings are a part of the General Science library in Ho Chi Minh City. Earlier, in the 1960s, public libraries began to establish a network of town and district public libraries.

Years of turmoil in the country have taken a toll on the development of information services, and many segments of the system of information services are attempting rapid recovery. This recovery is being aided by a number of international organizations working with various information services institutions. Those international efforts include UNESCO, International Federation of Library Associations and Institutions (IFLA), and other who have contributed substantially by advising and encouraging an efficient library and information services infrastructure in Vietnam. Vietnamese librarians are becoming more involved in international professional activities, including those of IFLA, the Congress of Southeast Asian Libraries, UNESCO, and other. In addition, philanthropic organizations have supported both the development of libraries and the education of librarians, primarily Atlantic Philanthropies which has contributed in the form of financing the development of state-of-the-art Learning Resource Centers (LRCs) in major universities in the country (Can Tho, Da Nang, Hue, and Thai Nguyen). They, along with Harvard Yenching Foundation, and others have supported the graduate education of over 50 master's degree students at Simmons College in Boston, United

States of America—under the educational direction of Dr. Patricia Oyler—and of other programs at the University of New Zealand in Wellington. Many of those graduated librarians are now in leadership positions in academic libraries and information center throughout the country. Dr. Oyler has been recognized by the Vietnamese government, as has Mr. Michael Robinson, formerly of Atlantic Philanthropies, as international colleagues who have made significant contributions to library and information services in the country. Librarians have also received archival and librarianship training in several other countries—Australia, Japan, Great Britain, and France among them. UNESCO has been supportive of many preservation efforts in the library community.

Several library organizations are involved in digitization projects, including: the National Library (digitization of abstracts of thesis), National Center for Scientific and Technological Information (NACESTI) (digitization of technical reports); Han-Nom Institute (digitization of paper rubbings of Han Nom steles); Vietnam National University (VNU) (digitization of course packs for students), Natural Sciences Library, Ho Chi Minh City (sponsored translation of Greenstone software into Vietnamese); and General Sciences Library (GSL) (digitization of SaiGon-HCMC Collection).

Today, all libraries and information centers in Vietnam operate under the Ordinance on Libraries, the highest legislation on library and information services passed in 2001 by the National Assembly of Vietnam with the intent to develop library resources and to increase state management efficiency in library activities. Another piece of legislation affecting information services, augmenting the 2001 ordinance, was passed by the Vietnamese National Assembly on November 20, 2005. That law relates to intellectual property for noncommercial purposes—including cultural exchanges or propaganda—indicating the fact that permission need not be obtained from creators/owners or royalties paid. This enhanced information services provided by nonprofit libraries and information centers. It addresses rights and responsibilities of organizations and individuals in library activities; library organization and operation; library investment and development; state management on library development; reward and handling violation in library activities; and implementation provisions.

Libraries are organized by category and/or type and are the responsibility of four different government ministries. Academic libraries and school libraries are discussed under one topic, since they are both under the supervision of the Ministry of Education.

The four categories are: public, academic, school and special

Public Libraries

The current public libraries system was set up in 1954, after the Indochina War. The system includes not only the National Library, but also provincial libraries located in

capitals of the provinces, district libraries located in capitals of the districts, and village libraries. The public library system supports many literacy efforts through the development of programs—children’s art exhibits, book exhibitions, reading classes, story-telling, lectures on important topics, and mobile services to remote areas of the country.

The Public Library System, administratively under the Ministry of Culture and Information, now the Ministry of Culture, Sports, and Tourism, is organized at four levels, correlating to levels of government. They include:

- NLV
- 64 provincial libraries of the 64 province administrative units
- 589 district libraries within the 633 district administrative units
- 8677 ward and commune libraries, including Reading Rooms for Children and Village libraries or book cabinets^[7]

The NLV

The primary public library unit in the country is the NLV.^[8] The impetus for a National Library, as indicated above, was establishment, by the General Governors of Indochina on November 29, 1917, of the Central Library, located in Saigon. The National Library in Hanoi was named NLV by the Provisional Revolutionary Government of the Democratic Republic of Vietnam on October 22, 1945. However, it was not until the 1960s that Vietnam began further development of the central collections of the NLV in Hanoi. The Library has the statute at the Department level within the Ministry of Culture and Information, now renamed the Ministry of Culture, Sports, and Tourism. The NLV is now organized and operated in accordance with the Government’s Resolution No. 401/Ttg dated September 9, 1976 on the Library’s Functions, Targets, and Missions. This Ordinance was amended by the National Assembly in 2001. Its adoption of the intellectual property law went into effect on July 1, 2006. A new library building was completed in 2001, adding to the infrastructure of the Library.

The National Library serves as the primary depository of the nation’s recorded history. Its charges include:

- Compiling and publishing the national bibliographies of Vietnam
- Developing and preserving a national Vietnamese collection by deposit of domestic publications, doctoral thesis, and patents
- Collecting relevant foreign materials of different forms, on Vietnam and works of Vietnamese living abroad, as well as manuscripts of famous Vietnamese writers through purchase and exchange
- Organizing materials and developing an information reference system to serve readers as the nation’s information centre for culture and arts

- Publishing monthly and annually national bibliographies of Vietnam
- Maintaining an awareness of new developments in order to provide professional guidance to the public library community nationwide
- Providing professional guidance to all library systems nationwide; especially the public library system through the establishment and administration of the Local Area Networks and the Wide Area Networks (WANs) of the public library system, and carry out R & D projects on library and information sciences
- Coordinating library activities such as acquisition on foreign periodicals and books, union catalogs, and carry out interlibrary loan^[9]

In 2005, NLV completed the national project “Building the National Electronic/Digital Library in the NLV” which was begun in 2001 and most major public and academic libraries and information centers have now joined that Integrated Library System.

The *National Bibliography of Vietnam* has been a production of the Library since 1955 and compiled monthly and annually. Since 1997, the NLV has been developing and maintaining a WAN system for public libraries in accordance with Resolution No. 579 by Ministry of Culture and Information. It has adopted and adapted MARC21 for its own use and that of the public library system. In 2006, under contract with OCLC (Online Computer Library Center), the NLV began, and has now completed, translating the Dewey Decimal Classification, Abridged Edition 14 into Vietnamese for use by libraries in the country. It provides some computers with peripheral equipment and photocopy machines for each provincial library. The National Library is also supporting an international effort to develop the Vietnam Union Catalog in an effort to create an international union list of Vietnamese *quoc ngu* titles held in Vietnam’s major libraries.

The National Library maintains several databases, including:

- The book (SACH) database, which contains records of books in Vietnamese and Latin languages from 1950 to the present time, as well as some books in Cyrillic, Chinese, and Japanese script.
- The serial publications database (JM) which includes records of serial publications, acquired by NLV since its establishment to the present. This database contains newspapers and magazines in Vietnamese and foreign language, including serial publications in Cyrillic characters.
- The thesis database (LA) which contains records of over 5500 doctoral dissertations by Vietnamese citizens in Vietnam and abroad. This database contains half of the total number of thesis stored in the NLV.
- The newspaper and periodicals of Indochina database (NCUU) which includes about 1700 titles.

GSL

The GSL in Ho Chi Minh City, formerly Saigon, is the other major public library in Vietnam and is the genesis of the original national library established by France in the nineteenth century. The term “general sciences” is a misnomer in the library’s title, since the library serves the primary role of an open public library with extensive services to the general public, to schools and to other public libraries in the area. In addition, it is an important preservation center, including archives and preservation facilities. Founded over one hundred years ago as the Library of the Admirals and Governors, the library was later recognized as the National Library of South Vietnam. It now possesses over 1.5 million books.

In the international arena, the library acts as a deposit library for UNESCO, World Bank, the Food and Agricultural Organization and the International Atomic Energy Agency. It is responsible for collecting and maintaining materials of all kinds published inside and outside the country. The library, under the former dynamic leadership of Ms. Nguyen Thi Bac, now reaches over 150,000 users yearly. Ms. Bac, a Simmons graduate of 1994, took early retirement in 2008, to work with several Scandinavian NGOs and is now country director for the Right to Read Foundation.

In addition, the library supervises 24 district libraries in the city and provides professional support to 21 provincial libraries. With Ho Chi Minh City being the country’s center of business and commerce, no other public library in the country has as much activity, including an extensive exchange program with international agencies, overseas acquisitions, and constant use of the collection by scholars from abroad. It publishes the journal *Library Information Bulletin of South Vietnam*.

General Sciences Library has a unique and extensive collection of Vietnamese materials from 1954 to 1975 and the Library is working with the NLV, the legal depository, to include those holdings in the database of Vietnamese publications. Notable special collections of over 400,000 volumes include seventeenth and eighteenth century French/European and Indochinois materials. Notable services include model programs for the visually impaired, titled “Library for the Blind” project, and a state-of-the-art digitizing and microfilming services, as well as archives and preservation center.

Other Public Libraries

Other large libraries include those in Hanoi and Hue. In recent years, more than 1500 new public libraries have been created—as Cultural Village Bookcases, Pagoda Libraries, Bookcases of Commune Cultural Post Offices, etc. More than 150 mobile libraries have been developed within the last few years, as well as such activities as

Libraries on Boats, Book Bags for Border Guards, Bookcases in Communes, Cultural Post Offices, etc. This is in support of promoting culture and information in remote and rural regions.

Academic Libraries

The administration of both university and general educational/school libraries is under the jurisdiction of the Ministry of Education and Training. There are 45 academic libraries in Vietnam under the Ministry of Education and Training. In addition, there are a number of international universities, such as the RMIT (Royal Melbourne Institute of Technology) National University Vietnam, located in Ho Chi Minh City, whose libraries are under the regulations of those international governments or organizations.

All academic libraries are administratively under the Ministry of Education and Training. Several digital library projects are in the planning stages or being implemented, including the e-Book project at the VNU, Hanoi, Library and the use of the Greenstone Digital Library open source software at the VNU, Ho Chi Minh City University of Natural Sciences Library. Integrated library management systems have been or are being implemented in many of the academic libraries.

There are two academic library associations: NALA—The Northern Academic Library Association of Universities and Colleges (Hanoi) and FESAL—The Federation of Southern Academic Libraries (Ho Chi Minh City).

On February 12th, 2001, Decision No. 15/2001/QĐ-TTg reorganized the two national universities in the country: they are each amalgamations of 10 previously existing higher education institutions. Libraries within those amalgamated universities are:

VNU Hanoi Library and Information Center

Vietnam National University now provides information services for all colleges and member units within its system. The university, itself, has had several name changes over the years: the University of Indochina (established in 1906); VNU (Dai hoc Dong Duong, established November 1945); the University of Hanoi (Dai hoc Tong hop Ha Noi, June 1956). This University’s unified Library and Information Center was established in 1997 on the basis of amalgamating the libraries of the University of Hanoi (previously named the College of Social Science and Humanities), the College of Natural Science, and the former Hanoi Foreign Language Teachers’ Training College, currently named the College of Foreign Languages.

VNU Ho Chi Minh City Central Library

Vietnam National University Ho Chi Minh City was founded in 1995 by a government decree 16/CP and now consists of five universities and one faculty. The library

system of the VNU Ho Chi Minh City consists of the Central University and one library in each of the universities which make-up the system.

Other Academic Libraries in Vietnam

Several universities have been provided with new library buildings called LRCs have been provided with new library buildings, with a substantial information infrastructure, including technology and access to on-line resources, through grants from Atlantic Foundation. Those LRCs are located in: Can Tho University, Da Nang University, Hue University, and Thai Nguyen University. These projects of developing state of the art academic resource centers have been implemented through contracts with RMIT in Australia, and the professional staffs have been educated with master's degrees in library and information science, primarily through contracts with Simmons College in Boston, Massachusetts, United States of America.

School Libraries

Some 17,000 school libraries about half of the secondary schools have libraries, with an equal number in elementary schools. Organizations, such as Room to Read, are working with local area residents to create school libraries in villages. Over 160 such libraries have been created in Vietnam.^[10]

Scientific, Technological and Other Special Libraries and Information Systems

Most special scientific and technical libraries are under the Ministry of Science, Technology, and Environment. There are approximately 60 research libraries run by research institutes and 218 other special libraries. Other special information centers are under various ministries or other governmental agencies.

National Agency for Science and Technology Information of Vietnam

According to the Government Degree number 28/2008/ND-CP, dated March 14, 2008, on the functions, responsibilities, authorities, and organizational structure of the Ministry of Science and Technology in Vietnam, what was formerly known as NACESTI has been changed to the National Agency for Science and Technology Information of Vietnam, NASTIV, with added responsibilities. The organization was originally established in accordance with the Decision No. 497/TCCB dated September, the 24th, 1990 by the Chairman of the State Committee for Science on the basis of merging two former organizations: the Central Library on Science and Technology (Founded in 1960) and the Central Institute for Scientific and

Technical Information (founded in 1972). Under Dr. Ta Ba Hung's leadership NASTIV is the primary force in the development of scientific and technological information services in the country. One activity of particular importance for information services is that both MARC21-VN and AACR2 were translated by NASTIV Added responsibilities, under the new designation, include:

- Management of Science and Technology Information Network in Vietnam
- Management and implementation statistical data on Science and Technology
- Management and operation of Vietnam Research and Education Network (VinaREN)

Its primary role is to manage and coordinate scientific and technological library activities in the whole country and formulate national S & T information and Documentation Policy. National Agency for Science and Technology Information of Vietnam serves as the leading center of the national information system on scientific and technological information and documentation and has responsibility for managing overall scientific, technological, and environmental information and documentation activities in Vietnam. It, therefore, has a twofold mission: management of S & T information activity and serving as the national information center for science and technology^[11] by providing traditional and electronic library services to readers.

Since 2001, NASTIV's Library has subscribed to hundreds of online e-journals in the applied sciences, business, and management. In order to facilitate information sources sharing, NASTIV established VISTA (Vietnam Information for Science and Technology Advance)^[12] in 1997. This is a nationwide information network that is playing an important role in resource sharing and meeting the information requirements of scholars and the SME community in Vietnam. Through VISTA various types of information, collected, or produced by NASTIV, are distributed to those who can access the Internet. Through VISTA, all 61 provinces are interconnected for sharing information on science and technology by leased lines or by dial-up through the public telephone lines.

National Agency for Science and Technology Information of Vietnam has been a leader in digital library development as a major trend in library and information services development in Vietnam. This is an approach strongly supported by both high-ranking policy-makers and library communities. In 2007, it hosted—along with the NLV, General Science Library of Ho Chi Minh City (GSL), the Library & Information Center of the VNU Hanoi (LIC/VNUH), Hanoi University of Technology, Vietnam Association on Scientific and Technological Information & Documentation (VASTID), Vietnam Library Association (VLA), Vietnam Association for Information Processing—the 10th International Conference on Asian Digital Libraries with the theme “Asian Digital libraries.”

In order to meet the urgent needs of Internet users for digital information in the Vietnamese language and in English, NASTIV publishes a number of electronics bulletins and e-journals that are accessible over the Internet. National Agency for Science and Technology Information of Vietnam's major databases include: the Central Library for Science & Technology Catalog, a multidisciplinary database that reflects a rich Vietnam collection of monographs on science and technology; SCITEC, a foreign multidisciplinary scientific and technological documents database covering journal articles and conference proceedings; KQNC, a domestic R & D projects reports database that reflects completed R & D projects financed by the government budget; STD, a comprehensive multidisciplinary database on science and technology that covers domestic periodicals' articles, conference proceedings; and VNDOC, the Vietnam Science and Technology Abstracts (in English); as well as a Foreign Periodicals Union Catalogue Database, covering the holding information on about 6000 foreign periodicals titles available in about 40 leading information centers and libraries in the country.

The National Center for Social Science and Humanities Library

The National Center for Social Sciences and Humanities of Vietnam, was originally set up in 1975 with the mandate to develop and maintain a collection of research materials. In 2004, it was renamed the Vietnamese Academy of Social Sciences (VASS). Within VASS there are roughly twenty seven institutes and centers. This main library is located at the Institute of Social Science Information. Each institute, likewise, has its own library. Today that library has the largest collection in the country of social sciences and humanities materials. It preserves many valuable documents, including ancient books, handwritten documents, very precious photographic materials, etc. It is a leader in library and information activities of the social sciences and humanities. The Center itself serves 16 institutes, seven research centers, a museum of ethnology, and various research support offices.

The Central Institute for Medical Information and Libraries

The Ministry of Health Library was set up in 1979 on the foundations of the former Central Medical Library. The Institute's library is the leading medical-pharmaceutical information institution in Vietnam responsible for using information technologies in providing medical library and information services; providing the health and medical information; training and guiding the library and information in the medical library and information system throughout the country. It is also the national focal point

for international relationships in the medical library and information area.

The Military Library System

Section 4 of Article 19 of the government's Ordinance on Libraries^[13] states that "Libraries of the people's armed force units" are established to serve the demands of officers and men with such units, and may serve other subjects according to such libraries' regulations. The system of military libraries is under the Ministry of Defense and includes some 1500 libraries and mobile unit libraries. Of them there are 54 main libraries, each with a collection of from 200,000 to 300,000 volumes.

LIBRARY AND INFORMATION SCIENCE EDUCATION AND TRAINING

Education and training of information and library services staff is promulgated at several levels:

- Certificate of Library Technician, awarded to those who have completed secondary vocational school.
- Bachelor of Library Science, Bachelor of Information, Library and Computer Science: for undergraduates who have successfully completed university. A diploma for "Scientific and Technological Information Engineers" is under consideration.
- Master of Library Science awarded to graduates who have completed the post-graduate requirements.

Master of Library and Information Science programs are offered at some universities. Most universities or colleges now offer the bachelor's degree, the basic educational degree for librarians in Vietnam. Some offer diplomas. Five higher education institutions offering library and information science programs are:

VNU Hanoi, University of Social Sciences and Humanities

Faculty of Library and Information Science

The newly designated faculty was established in 2004. However, the program continues a tradition of education and scientific research first developed by the Department of Library Science which belonged to the Faculty of History—Hanoi University, established in 1973, and later designated as the Department of Library and Information Science—University of Social Sciences and Humanities (USSH), VNU in 1996. Since that earlier time the University has been training undergraduate students at this Hanoi campus. The primary goal of the faculty is one of educating both undergraduate and postgraduate students and developing their professional skills and theoretical

knowledge relating to library and information science. Currently both graduate and doctoral programs provide deeper insights, methodologies, and analytical skills in library and information science.

The Hanoi University of Culture

The Hanoi University of Culture was established in 1961 as the Cultural College of Hanoi on the foundations of the former Cultural, Theoretic, and Professional School. From its beginning it has trained library technicians and undergraduates who received a diploma, and since 1991, the University has offered the master's degree in Library Science. Unlike other higher education institutions the cultural university reports to the formerly named Ministry of Culture and Information, now the Ministry of Culture, Sports, and Tourism, and is responsible for training vocational students as well as undergraduates in areas that include culture, library science, and museology.

VNU Ho Chi Minh City USSH

School of Library and Information Science

The unit was established in 1976, from the former Saigon University of Sciences. The Faculty of Library Science was set up in 1986–1987 to offer a Bachelor of Library Science program for the Southern provinces. The School now prepares students for three degrees: technician, undergraduate, and postgraduate.

The Ho Chi Minh City College of Culture

The College was established in 1976 to train secondary vocational level students in the cultural professions. This College, as with the Hanoi University of Culture, reports directly reports to the Ministry of Culture, Sports, and Tourism. Since its establishment, it has trained library technicians. In 1985, it has been allowed by the Ministry to enroll students for short-term courses to train librarians for Southern provinces. It also offers a certificate program.

Can Tho University Learning Resources Center

Library and Information Management Program

This new program, established in 2006, is an undergraduate program educating library and information science students, particularly from the Mekong Delta area.

Several other organizations, including the National Library, NACESTI School of Central Archives and the Army Libraries, offer training programs on topics of importance in educating professionals responsible for providing information services.

THE VLA

The original VLA (Hoi Vien VietNam) was founded in 1959 but was in existence only a couple of years. It was reestablished in 1968 and was in existence until 1975.

The recently reinstituted VLA, the nationwide grouping of Vietnamese librarians, was officially founded on October 22, 2006 with more than 300 librarians and information professionals representing all types of library systems in the country. According to the Association's Charter, the VLA has the objectives to: Advance and strengthen Vietnamese librarianship; enhance the roles and positions of librarians and library institutions in the Vietnamese people's social and cultural life; make positive contributions to the economic, social, and cultural development of the country. Vietnam Library Association also strives to:

- Establish, maintain and strengthen networks, partnerships and linkages among Vietnamese and foreign librarians, libraries, library schools, and library associations and related organizations in order to share and improve professional knowledge; foster the development and international integration of Vietnamese librarians and library institutions.
- Serve as a national forum for library professionals, library related people and library friends to share experience, to promote mutual understanding, and to unite their intellectual power to solve major issues of the Vietnamese library professions.

Vietnamese Library and Information Science Journals

Two primary journals relating to library and information services in the country are:

- *Vietnam Library Journal* (Tap chi Thu Vien VietNam), revival of the previously published *Library Bulletin* (Tap San Thu Vien) National Library of Vietnam, Hanoi, Quarterly, 2007.
- *Journal of Information and Documentation* (Tap San Thong Tin Va Tu Lieu) NACESTI, under the Ministry of Science, Technology and Environment, in Hanoi. Quarterly, 1990—This journal is in Vietnamese with abstracts in English. It is also published online. (<http://www.vjol.info/>).

Other journals and newsletters include:

Southern Library and Information Newsletter (Thong tin & Th vien phia Nam). General Sciences Library Association for Library Information Science & Documentation.-Ho Chi Minh City, semi-annual; 1993–

Library-Information Technology Newsletter (Ban tin Cong nghe Thong tin Th vien): University of Natural Sciences.— Ho Chi Minh City. Monthly 1998—(<http://www.glib.hcmuns.edu.vn>).

National Technology and Science—Information and Documentation Center Newsletter (Ban tin Trung tam Thong tin—T lieu Khoa học va Cong nghe Quoc gia) Ministry of Science Technology and Environment.— Hanoi, Quarterly, (<http://www.vista.gov.vn>)

Newsletter of Pedagogical College of Ho Chi (Minh City Ban tin th vien), Monthly; 2002—

ARCHIVES

Manuscripts formed the basis for the first archival collections and have existed since the Ly dynasty in the eleventh century. An exact date has not been determined for the introduction of printing, the use of wooden blocks and boards, began sometime after the beginning of the twelfth century. During the twelfth to seventeenth centuries there was development of archival collections, primarily under the Tong (1460–1497) dynasty. However, official archives had been kept from the early days of the kings of Dai Viet, so that by the time of that Nguyen Dynasties (1802–1945) a substantial repository for official documents existed under the administrative control of a state office for libraries and archives. This repository housed both manuscripts and printed materials in cur Han (classical Chinese, the official language of the court until the early years of the twentieth century) and later the ideographic *chu nom* and romanized *quoc ngu* scripts, including land records and official court documents known collectively as *chau ban*. This was a substantial repository for official documents under the administrative control of a full-blown state office for libraries and archives. Most of those materials have not survived and, indeed, only about 5% of pre-1802 Nguyen dynasty (1802–1945) materials have survived. Approximately three-quarters of all Nguyen dynasty court records were destroyed during the First Indochina War of 1946–1954. Those which survived and are still in the country are in the National Archives Center #1, National Archives Centre #2, and the Institute of Han-Nom Studies Library in Hanoi.

Record keeping, of a more western approach, was introduced in the 1860s by French colonial authorities who enacted legislation to archive documents of national importance. During the early years of the colonial period, French government documents were stored in a variety of different government offices throughout the country. However, following the decree of the Indochinese General Governor, the Central Archives, and Library of Indochina was set up in Hanoi in 1917, with satellite archives in Saigon and Hue. Some few wood-block printed editions,

of earlier Buddhist texts, dating from the 1650s, are now in the National Archives in Hanoi. The majority of those surviving documents date from 1802, when the last ruling dynasty, the Nguyen (1802–1945), was in power. After 1954, the depositories in Hanoi and Saigon, respectively, housed the state archives of North and South Vietnam.

The current system of state archives dates from September 8, 1945 when the Provisional Government of the Democratic Republic of Vietnam issued a Decree establishing a National Service of Archives, Official Documents, and Libraries under the Ministry of Education. Shortly thereafter, on January 3, 1946 President Ho Chí Minh signed Circular 1C-VP, which emphasized the special values of archival materials in the task of national reconstruction. That decree prohibited destruction of any official record without the consent of competent authority.

Prior to 1962, the northern archives operated as a branch of the National Library, but Decree 102/CP of that year set up a separate National Archives Department within the Prime Minister's Office. Following Reunification in 1975 the public records office in Ho Chi Minh City became National Archives Centre 2. Today all of the older holdings of the Vietnamese National Archives are stored in these two repositories. A state-of-the-art new repository—National Archives Center 3 was opened in April 2002 to house the records of national, regional, and interregional agencies and institutions of the Democratic Republic of Vietnam (1945–1976) and the Socialist Republic of Vietnam (1976–present).

In 2003, the National Archives Department was renamed the State Records and Archives Department of Vietnam.

The northern archives operated as a branch of the National Library until 1962 when Decree 102/CP set up a separate National Archives Department within the Prime Minister's Office. At that time the old colonial records office on the grounds of the National Library became an annex known as National Archives Center #1. Following Reunification in 1975, the public records office in Ho Chi Minh City became National Archives Center #2. Today all of the older holdings of the Vietnamese National Archives are stored in these two repositories. A new state-of-the-art repository, the National Archives Center #3, was opened in April 2002 to house the records of national, regional and interregional agencies and institutions of the Democratic Republic of Vietnam (1945–1976) and the Socialist Republic of Vietnam (1976–present).

State Records and Archives Department of Vietnam

On January 25, 1991 Decision 24-CT of the President of the Council of Ministries made the Archives State Department responsible for the management of archives activities in the country and in 1992 the State Archives was placed under the Government Committee on Organization and Personnel, Ministry of Home Affairs. On April 4,

2001, the National Assembly's Standing Committee passed the Ordinance on National Archives. Cultural Heritage Law and in 2003 the National Archives Department was renamed the State Records and Archives Department of Vietnam.

The State Records and Archives Department of Vietnam consists of a network of some 70 provincial and municipal archives which are responsible for keeping, caring for and making accessible records of the events and decisions that shaped the nation, including central and local records of the Viet kings, the French colonial government, the US-backed Government of South Vietnam, the Democratic Republic of Vietnam, and the Socialist Republic of Vietnam.

However, the most important archival and printed texts, under public control, are held in those repositories in Vietnam including the National Archives centers, two in Hanoi and one in Ho Chi Minh City, and the three research institutes in Hanoi, under the control of the National Center for Social Sciences and Humanities, those being: the Sino Nom Research Institute; the Historical Institute; and the Social Sciences Information Institute.

Other major collections, as previously mentioned, are in the National Library in Hanoi and the GSL in Ho Chi Minh City. Some materials also can be found in several other archives and libraries, including the Archives of the Central Committee of the Communist Party, the Army Library, the former library of the Pasteur Institute, and several provincial repositories^[14] as well as archives in various ministries, however declassified noncurrent records of the Ministries of Foreign Affairs, Defense, and Public Security are transferred to the National Archives Centers after 30 years. Other government organizations also maintain some archival records as do some provincial archives centers, and some professional organizations, as well as academic units within universities. For instance, special archives include the Institute of Music Sound Archive, the cinematic archives of the Vietnam Film Institute, and archives of the Vietnam Buddhist Association and the Catholic Church in Vietnam.

The State Records Management and Archives Department of Vietnam is responsible for, among other things:

- Developing long-term and short-term plans for archives development on a country-wide basis, as well as directing and controlling their implementation.
- Directing research work and application of scientific and technological advancements into archival work.
- Conducting training and retraining for records management and archival work personnel; regulating emulation and rewards in archival activities.^[15]

In order to preserve safely and make full use of archives, one of the primary measures directed by the SADV (State Archives Department of Vietnam) is to reinforce the application of information technology in archives

work. It has established databases to serve the management, multiuser access and security preservation of some valuable Chauban (Emperor's records), Mocban (Woodblock records) of Nguyen Dynasty, and sound recordings, on CD-ROM.

The National Archives

The National Archives operates as the chief agency of the archives sector in Vietnam with the mission of carrying out the unified and centralized administration of archival work and archival national records at the nationwide level, including the task of applying information technology in the archives domain. It is responsible for organizing, guiding, and inspecting the implementation of government regulations on archives and records management. With that responsibility it manages the holdings of the State Records and Archives Department, including (instructing, selecting, preserving, and utilizing records at the National Archives Center as well as historical archives and at archives of all government agencies.^[16] The three centers are:

National Archives Center #1 in Hanoi is responsible for collecting, acquiring, preserving, and making effective use of archival records of national significance from feudal times (with the exception of woodblock records), including the French colonial period. It includes 60 archive collections and records groups, plus a range of books and materials dating from 1488 to 1945, including: Han-Nom (Chinese and Sino-transcribed Vietnamese) records produced by the feudal dynasties of Vietnam, principally royal records (and land records of the Nguyen kings and records of the Royal Viceroy in Tonkin and what is now Hanoi from 1802 to 1945; Records of the French colonial administration from 1858 to 1945, and records produced by the French-backed administrations in the north of Vietnam between 1945 and 1954 and historical books, periodicals, reviews, and official gazettes published prior to 1945.

National Archives Center #2 in Ho Chi Minh City is responsible for collecting, acquiring, preserving, and making effective use of archival records of national significance from the feudal period and from the French colonial territories of Annam and Cochinchina, the southern region of Vietnam including 55 archival collections and records groups, disks, sound recordings, and photographs and negatives dating from 1802 to the present, including: administrative records produced by the Governors General of Cochinchina, the Governors of Annam, the U.S.-backed Government of South Vietnam and various revolutionary organizations established in the south after 1975. It also houses scientific and technological records such as maps and atlases dating from 1862 to 1975; audiovisual records, photographs, films, newsreels, and sound recordings produced before 1975; woodblock records of various books and bibliographies produced by

the Nguyen dynasty (1802–1945), and a collection in Han-Nom (Chinese and Sino-transcribed Vietnamese).

National Archives Center #3, opened in 2002) in Hanoi, is responsible for collecting, acquiring, preserving, and making effective use of archival records of national significance created by central, regional and interregional agencies, and institutions of the Democratic Republic of Vietnam (1945–1976) and the Socialist Republic of Vietnam (1976–present), which includes administrative records produced by state central agencies and institutions such as the National Assembly, Government, Ministries, and regional and interregional committees from 1945 to the present; scientific and technological records, including records of the design and construction of important national works such as the Ho Chi Minh Mausoleum, videotapes and documentary and newsreel films of historical value; and personal papers and records, including personal papers, manuscripts of creative works by famous scientists, writers, artists, and political figures.

Besides those three archive centers, the Department also operates a Center for Scientific Research, an Information Technology Center, a Center for the Secure Preservation of National Archives and two secondary level training schools—the Central Secondary School of Records Management and Archives in Hanoi and the Central Secondary School of Records Management and Archives in Hồ Chí Minh City.

Those centers house only limited materials of potential significance for Cold War scholars.^[17] The post-1945 section of the National Archives in Hanoi contains documents generated prior to 1975.^[18,19] The National Library houses the primary collection of materials relating to the records of war in the country, which were produced in various resistance zones from 1946 through 1954.

Center for Conservation and Restoration of Archive Materials

The Center^[20] was established in 1993 to function as a repair and restoration center for the records of the national archive centers and various other institutions. Its primary responsibilities are: preparing and implementing long-term and short-term plans for the restoration, disinfection, fumigation, and deacidification of national archive records; coordinating with other organizations and individuals in identifying records and archives in need of conservation measures; receiving materials and undertake the necessary conservation and restoration work, ensuring that works are safeguarded during the process; and participating in studies toward and applications of scientific and technological advances in the conservation and restoration of archives. UNESCO has worked with colleagues at the center, and others in Southeast Asia, to address primary issues, including “Cultural Heritage Management.”

Institute for International Affairs

This Institute in the Ministry of Foreign Affairs maintains the archival materials of the Cold War period, but those materials remain primarily inaccessible to both Vietnamese and foreign researchers. Collections of materials for that period are in the Foreign Ministry, Communist Party, and Army collections and have not been deposited into the National Archives.^[21]

Vietnamese Record and Archives Association

The Association was founded under Decision 28/2001-QĐ-TCCBCP issued on May 23, 2001 by Minister-Chairman of Government Committee of Organization and Personnel as a social/professional organization representing Vietnamese individuals and organizations engaged in the archives profession and other concerned branches.^[22] It is chaired by the Director General of the Department. The Association’s aims are to:

- Assemble and unify members for exchange and dissemination of professional knowledge and experience.
- Enhance professional capacity.
- Coordinate with institutions and organizations engaged in archival profession to contribute to the development of Vietnamese archives in order to preserve safely and make effective use of national archival records for the national construction and defense of the Socialist Republic of Vietnam.

Archival Journals

Vietnam Records and Archives Review is published bimonthly by the Vietnam Record and Archives Association as a forum for research, instruction, guidance, and the exchange of information and experience on records management, archival, and office work.

Vietnam Records and Archives Magazine is published bimonthly by the State Records and Archives Department of Vietnam. The journal is similar to *The American Archivist* in that it contains articles on archival theory and practice, and also highlights specific projects in state archives centers around Vietnam. The journal publishes, among other topics, articles describing current practices and trends in archival science, including digital access and preservation of electronic records.

Archival Studies Education

In 1968, an archives education program was begun within the history department of Hanoi University, to train archivists at the tertiary level. In 1996, it became a separate “Faculty of Archival Studies and Office Management” in the University of Social Sciences and Humanities within

the VNU complex. Both a 4 year BA and a 2 year MA program are offered.

In 1974, the Archives Department of Vietnam founded a secondary school in Hanoi—the Central Secondary School of Archives and Office Skills 1—to train records and archives staff at intermediate level. A second school was opened in Ho Chi Minh City—as the Central Secondary School of Archives and Office Skills 2—in 1979. They both offered Secondary Certificates in Records and Archives Management. The one located in Hanoi was upgraded in June 2005 to a college level degree. In addition, the State Records and Archives Department of Vietnam and the Association of Vietnam Archives also provide regularly the short-term intensive training courses in archives.^[23]

MUSEUMS

History

The concept of the museum in Vietnam was introduced by the French who founded the Mission *archéologique d'Indochine* in Saigon (now Ho Chi Minh City); in 1901. It later moved to Hanoi and became the EFEO, with the aim of describing the archaeology of French Indochina, conserving its monuments, collecting its manuscripts, and undertaking research into the region's linguistic heritage. The first museum was developed in Hanoi in 1910 to display archaeological and ethnological artifacts, and paraphernalia from the Nguyen kings, including particularly royal regalia.^[24] The scholarly work of the EFEO provided the groundwork for the establishment of the Cham Sculpture Museum (1915–1916) in DaNang; the Musée Louis Finôt (1926), now the Vietnam History Museum in Hanoi and the Musée Blanchard de la Brosse (1927), now the Vietnam History Museum in Ho Chi Minh City. After 1954, the *Musée Blanchard de la Brosse* in Saigon became the National Museum of South Vietnam, but prior to 1975 no other museums were constructed by the South Vietnamese authorities.

During this same period in the north the Musée Louis Finôt became the Vietnam History Museum and a number of new museums were established—the Museum of the Vietnamese Revolution (1959), the Vietnam Military History Museum (1959), the Vietnam Fine Art Museum (1966), the Museum of the Viet Bac Autonomous Region (1959)—now the Museum of Ethnology in Thai Nguyen—and the Hai Phong City Museum (1959).

Ministry of Culture and Information, through its National Cultural Heritage Department, formerly the Museums and Conservation Department, is assigned responsibility for managing the five national museums as well as for providing general professional guidance in the fields of conservation and museology at the national level. It is the governmental agency responsible for managing cultural

activities throughout the country, including museums, preservation of cultural heritage and libraries.^[25]

On June 29, 2001, the National Assembly adopted the current *Law on Cultural Heritage*, which acknowledges that cultural heritage plays a significant role in the continuing national development and preservation of the culture of Vietnamese people. The law states that “The State’s policies shall encourage work to collect, compile, translate, inventory, classify, and preserve works of literature, art, science, oral tradition, and folklore of the multi-ethnic Vietnamese community.”^[26]

In 1954, a separate Preservation and Conservation Department had been established and this unit became a Division of the Department of Cultural Heritage, following the introduction of a new law enacted in July 2003. This mandate was enacted in order to fulfill the objectives of preserving and promoting the country’s cultural heritage. The information technology section and information on archives section of the Department of Cultural Heritage are now integrated as an Office of Information and Documentation, with the future goal of providing an information system repository on national relics, using modern information technology. Several “virtual museums” are directed by another unit, the Division of Relic Management which administers five heritage sites that have been recognized by UNESCO as world heritage sites (Hoi An’s Ancient Town, My Son Sanctuary, Ha Long Bay, Hue, and Phong Nha Ke Bang Caves).

Vietnam currently has over 120 major museum institutions in which to date some 4 million objects have been inventoried and preserved. Five of these institutions are National Museums managed by the Ministry of Culture and Information. Some 30 others fall under the management of various other government offices, mass media organizations and agencies, including the Ministry of Defense (People’s Army of Vietnam), the Ministry of Industry, the Vietnam Academy of Social Sciences, the Vietnamese Women’s Association, the Pasteur Institute, the Oceanographic Institute, the Hoi An Centre for Monuments Management and Preservation, the Hue Historic Monuments Conservation Centre, and various tertiary training colleges. However, by far the greatest number of Vietnam’s museums—more than 90 in number—fall under the direct management of the country’s 63 provincial and municipal authorities.^[24] The overall system of Vietnam museums includes several categories, including national, provincial, and city museums; as well as those nongovernmental specific museums, and museums belongs to the armed forces.

Museology Education

A 4-year graduate training program in conservation and museology was initiated by the Faculty of History at the Hanoi National University during the 1970s. In the late 1980s, the program was transferred to the University of Culture in Hanoi as a Faculty of Conservation and

Museum Studies (*Trng Đại học Văn hóa Hà Nội*). The Hanoi University of Culture also has a training program on “Cultural Management.”

National Museums of Vietnam

National Museums under the Ministry of Culture and information. The National Museums are responsible for collecting, preserving, and exhibiting artifacts about the nation's history and culture. Five of these institutions are National Museums managed by the Ministry of Culture and Information.

Ho Chi Minh City Museum (Bao Tang Ho Chi Minh)

Located in a beautiful building was constructed in 1885–1890 by a French architect as a museum but became the Cochinchina Governor's residence. The Museum was opened on May 19, 1990, President Ho Chi Minh's birthday. Housed in a four-storey building designed in the shape of a lotus, the museum depicts the life and times of Ho Chi Minh and his major contribution to the founding of the Socialist Republic of Vietnam. The main showroom exhibits more than 2000 documents, articles, pictures, and exhibits illustrating not only President Ho Chi Minh's achievements but also the most important contemporaneous events that occurred throughout the rest of the world during his lifetime. The museum also incorporates a library and research rooms.

National Museum of Vietnamese Revolution (Hanoi) (Bao Tang Cach Mang)

As regulated in the Decision 37/2004/QĐ-BVHTT dated June 28, 2004 of the Ministry of Culture and Information, Originally established in January 1959, the Museum of the Vietnamese Revolution is housed in an elegant two-storey building formerly used by the Trade Department. It has been renovated and redesigned into 30 exhibition rooms which contain more than 80,000 historical artifacts. The first room presents Vietnam and the Vietnamese. The exhibition continues with exhibits on the national liberation movements of Vietnam against the French before the establishment of the Communist Party (1858–1930); the struggle for independence under the leadership of the Communist Party (1930–1975); and the construction and defense of the Socialist Republic of Vietnam (1976–1994).

Vietnam Fine Arts Museum (Hanoi) (Bao Tang My Thuat)

As regulated in the Decision 37/2004/QĐ-BVHTT dated June 28, 2004 of the Ministry of Culture and Information, Vietnam Fine Arts Museum has the responsibility of

conserving, exhibiting typical art work, materials, and objects of Vietnam. It was built in the 1930s by the French, and reserved for the French colonial rulers' daughters throughout the Indochina who came to Hanoi to study. In 1962, the government requested the Ministry of Culture to transform the building from the western architecture into a Vietnamese appearance with ornamental details from the traditional architecture of communal house and fit for exhibiting works of fine arts. On June 26, 1966 Vietnam Fine Arts Museum was officially inaugurated. Throughout 40 years, the Vietnam Fine Arts Museum has been the center for fine arts and culture study, contributing to the preservation and promotion of the nation's cultural heritage. It is an information services organization, directly affiliated to the Ministry of Culture and Information, whose role is one of conserving, exhibiting typical art work, materials, and objects of Vietnam. Objects and artworks date back to prehistoric times.

Museum of Vietnam History (Ho Chi Minh) (Bao Tang Lich Su)

The museum was originally established in the 1920s as the *Musée Louis Finot* and housed in a building which typifies the hybrid “Indochinese style” of architecture. The archeological collection includes relics from the Hung era and Neolithic graves, Bronze age implements, bronze drums from Ngoc Lai and Mieu Mon, Chom relics, stele, statues, ceramics. This museum traces the history of the Vietnamese people from the earliest times to the present day using displays of cultural and ethnological significance. Exhibits are displayed on two floors which cover an area of more than 2000 m.

Vietnam Museum of Ethnology (Hanoi) (Bao Tang Dan Ltoc Hoc)

This is both a research center and a public museum exhibiting the ethnic groups of Vietnam. Proposal for the Vietnam Museum of Ethnology was officially approved on December 14, 1987. On October 24, 1995, the Prime Minister made the decision on establishment of the Vietnam Museum of Ethnology, under National Centre for Social Sciences and Humanities. The Museum opened in 1997. The mission of the Museum is scientific research, collection, documentation, conservation, exhibition, and preserving the cultural and historic patrimony of the nation's different ethnic groups. The museum also serves to guide research, conservation, and technology that are specific to the work of an ethnographic museum. It is a vital museum in maintaining and promoting the treasure of cultural, artistic heritages of Vietnamese ethnic communities. As a center for ethnographic research the museum employing many experts on the different ethnic groups, located in Thai Nguyen.^[27]

Other Major Museums

Vietnamese Women's Museum (Hanoi)

Was dedicated on October 20, 1995, the 65th anniversary of the Vietnamese Women's Association, in honor of the brave Vietnamese women who had played an integral part in the social and political scenario of Vietnam. It honors the involvement of Vietnamese women in the fight for national independence and national construction. The Vietnamese woman is expressed through their struggle to liberate women, as well as exhibiting traditional handicrafts and costumes of the 54 Vietnamese ethnic groups.

Vietnam Military History Museum (Hanoi)

Military history from King An Duong era to the present day. Vietnamese victory of Dien Bien Phu showed the accomplishment of the Vietnamese people and army's protracted struggle against the French. On October 10, 1954, the Vietnamese army took Hanoi. In celebration, on July 17, 1956, an official decision was taken to form a board in charge of building the Army Museum. When war spread over the country, the Museum changed its direction corresponding to wartime, strengthening scientific research, preserving and protecting objects, collecting artifacts at battlefield. On December 12, 1959, President Ho Chi Minh, State and Party leaders came and inspected the exhibition then permitted holding the museum's opening ceremony on December 22, 1959 on the occasion of the 15th anniversary of founding the Vietnam People's Army. In 2002, the Army museum changed its name into the Vietnam Military History Museum.^[28] Its exhibitions present the Vietnamese military history from the first period of founding the country to the Ho Chi Minh era.

Geological Museum of Vietnam (Hanoi)

Geological Museum of VN now is an official member of the International Council of Museum, belongs to the Natural Scientific Museum system in VN. It is a leading national office, which conserves geological-mineral specimens. After the establishment of Geological Survey of Indochina in 1898, the two French geologists Lantenois and Mansuy received the task of building up the Geological Museum. In 1997, the Geological Museum was unified with the Institute for Geological Information and Documentation to form the Institute of Geological Information, Archives, and Museum, but in 2003 the Geological Museum was again separated from the Institute of Geological Information, Archives, and Museum.

ACKNOWLEDGMENTS

I would like to thank some of my former students, all of whom now occupy leading positions in the library and

information services professions in Vietnam. They include, particularly: Quan Mai Binh, Nguyen Huy Chuong, Nguyen Thi Bac, Dang Thi Mai, and Tran Thu Lan.

Visitor Studies

Susan Foutz

Jill Stein

Institute for Learning Innovation, Edgewater, Maryland, U.S.A.

Abstract

The field of visitor studies seeks to document and understand the experiences and outcomes of visitors to museums and other informal educational settings. Both research and evaluation studies help to inform what we know about visitors to these settings and the impacts of their visits. This entry explores the theoretical foundations, goals and objectives of the field, commonly used research methodologies, and what we have learned about visitors in museum-like settings.

INTRODUCTION

The field of visitor studies is grounded in the context of museums and other informal learning environments, such as science and nature centers, zoos, aquariums, gardens, national parks, IMAX movie theaters, planetariums, or libraries. The main objective of visitor studies is to understand how people benefit from and utilize these settings, and to help inform institutions in the development of exhibitions, programming, and other public education activities. In contrast to marketing research, visitor studies focuses on institutions and experiences that have a learning agenda or educational mission. This “learning” is defined broadly within visitor studies to encompass all levels of cognition, affect, skill development, and personal growth. Researchers in the field focus on the experience and impacts on the “whole person,” not just the learning of facts.
